Second-order quantification is quantification into the positions of predicates, rather than singular terms, in sentences. (See Second-order logic, philosophical issues in.) Such quantification might seem less obtrusive than uncountable individual quantification, but it also lets us say that there are uncountably many things, though framing the claim calls for a bit more ingenuity. But if the domains of models for formulas with quantifiers of either sort must be sets, then discourse with either sort of quantifier is subject to generalized versions of

Löwenheim-Skolem. Formal languages are usually distinguished by choices among countable infinities of individual constants, predicate letters and function signs. If so, there are only as many such languages as there are reals, and though there are lots of reals, they make up a set. So there are only that many theories, and thus satisfiable theories, too. To each such satisfiable theory assign the least cardinal that is the size of the domain of a model of the theory; all sets have cardinals, so if domains must be sets, this assignment works. Then (by the axiom of replacement) there is a set of all these least cardinals, and so a smallest cardinal greater than all of them. Whether we allow uncountable individual or second-order quantification, this cardinal is to those theories as the cardinal next after that of the natural numbers is to first-order theories according to the Löwenheim-Skolem theorem. For each is a size smaller than that of the intended world of set theory, yet each is a size larger than that of a world in which set theory comes out true. So long as the domains of models must be sets and languages distinguished by choices from a set of primitives, some such result seems inevitable whatever expressive devices we allow our languages; but if the domains need not be sets, it is unclear what they might be and how we might handle them.

Lu Xiangshan (1139-93)

A leading Chinese philosopher of the twelfth century, Lu Xiangshan was the founder of that dimension of neo-Confucian thought known as the learning of the heart-and-mind. Lu emphasized the necessity for personal responsibility and action in everyday affairs, as opposed to the search for moral understanding through classical texts.

Lu Xiangshan (named Jiuyuan, styled Zijing and popularly called Xiangshan) was a leading thinker of the Song dynasty (960-1279) philosophical movement commonly called neo-Confucianism (see Neo-Confucian philosophy). He is considered the founder of that dimension of neo-Confucianism known as the learning of the heart-and-mind (see Xin) and was an important rival of Zhu Xi, the pre-eminent twelfth-century philosopher and advocate of the learning of principle. Lu came from a large, multi-generational, elite family in south China that engaged in a medicinal drug trade, farming, local defence, social welfare projects and Confucian education. He attained the highest degree, served briefly but vigorously in office, and was famous for his teaching. His few writings, recorded sayings and biography are collected in the *Xiangshan quanji (Complete Works of Lu Xiangshan)*.

Critical of contemporary scholars' preoccupation with the civil service examinations and speculative ontological thought concerning *li* (principle(s) or pattern(s) of things) and *qi* (matter-energy) (see Li; Qi), Lu focused on actual human experience. Reflecting the importance of the *Yijing (Book of Changes)* (see Yijing) and Mencius in his thought, his primary concerns were the principles ordering the world (human society and nature) and the necessity for assuming personal responsibility for moral-social action.

Lu maintained that there is only one principle in (and one ordering source of) the universe. Shared by the 'three ultimates' of heaven, earth and humanity, this principle orders all things and affairs. It is the Way, the heart-and-mind, and human nature, and (as *qi*) does not exist apart from the world. Lu summarized his position in such claims as 'the heart-and-mind is principle' and 'my heart-and-mind and the universe are one'. This principle is public-mindedness and moral rightness, in contrast to selfishness and private profit.

Lu stressed the necessity to take responsibility for one's actions and to pursue Confucian learning in order to develop and implement one's moral-social nature. Emphasizing inner, natural capacities over outer, textual knowledge, Lu taught people to distinguish between morality and selfishness and to establish their aim. Echoing Mencius, he called this effort 'establishing one's greater part' (that is, the heart-and-mind). This kind of knowing was completed by moral-social action. In addition, a person should engage in constant self-examination and self-correction, while seeking help from reading and teachers and friends.

Scholars disagree about the interpretation of Lu's thought. Although some describe it as monism and subjective idealism, these Western labels are highly misleading because Lu was not concerned with the kinds of philosophical questions they imply, such as fundamental substances of being, objective-subjective reality, mind as consciousness and the unreliability of sensory knowledge.

Lucian (*c.* AD 120-80)

Lucian of Samosata (in ancient Syria) was one of the most original and engaging figures of post-classical Greek culture. He produced a diverse and influential corpus comparable in size to that of Plato (consisting of seventy-six authentic libelli). Formally the dialogue (in both Platonic and Cynic forms) dominates (thirty-six of seventy-three prose works), but there are also satiric narratives, tall tales (for example, A True Story), 'Cynic' diatribes (for example, On Mourning), and multifarious lectures, or essays (for example, The Master of Rhetoric) in his singular oeuvre.

Like other Greek writers in the Empire, Lucian is difficult to classify generically or ideologically. Who was this jester from the East, who dared ape the classics and yet succeeded in persuading posterity that he was, in the words of Macaulay, 'the last great master of Attic eloquence and Attic wit' (Macaulay)? A Hellenized Syrian of the Christian era who made Greek culture come to life as if were contemporary (Duncan 1979), Lucian was, none the less, not an absolute traditionalist: he parodied the classicizing literary fashions of Greeks in the Empire (such as 'Atticism' in *Lexiphanes*) and treated Greek ethnocentrism and the easy idealization of the classical past as targets ripe for satire (see for example, *Anacharsis, and Philosophers for Sale!*). Although long associated with philosophy, he was not a philosopher but a sophist, satirist and parodist, who, following Plato, the Cynics (for example, Menippus), and the Old Comic poets (for example, Aristophanes), took philosophers and their discourse as one of his principal subjects in a lengthy career as a writer and performer giving public readings of his work throughout the Roman Empire.

Lucian's work is philosophically significant in at least three senses. First, it is a source of ostensibly 'eye-witness' accounts of contemporary philosophical and religious figures, such as, the Cynic/Socratic Demonax of Cyprus, whom Lucian claimed as a teacher (in his *Life of Demonax*), the notorious Cynic Peregrinus of Parium and the 'false-prophet' Alexander of Abonoteichus, all of whom were extremely influential figures in their day and were, as such, mercilessly anatomized by Lucian in satiric narratives (*On the Death of Peregrinus*, *Alexander or the False-Prophet*) in which Democritus and Epicurus provide the philosophical armature. Second, he provides a general commentary on and evaluation of the reception of classical philosophical traditions in the polyglot cultural landscape of the Roman Empire. Lucian is suspicious of the inflated value of tradition(s) in a classicizing culture; accordingly, two works satirize the experience of 'conversion' to classical philosophical traditions (to Platonism in the *Nigrinus*, to Stoicism in the *Hermotimus* (compare *The Cynic*)). Similarly, the hilarious *Philosophers for Sale!*, in which the founding fathers of Greek philosophy are auctioned off as slaves, uses parody and caricature to satirize *all* the idols of the philosophers' tribe. (Lucian takes no prisoners: neither Diogenes the Cynic nor Pyrrho the Sceptic is spared satiric scrutiny, despite their own credentials as critics of philosophy.) The philosophical import of texts in these first two categories is more or less overt and explicit. Third, there are the philosophical implications of his practice as a seriocomic (*spoudogeloios*) writer of dialogue, satire and parody, which are generally Cynical or Sceptical in tendency. For example, in the *Anacharsis* two legendary sages (Solon the Athenian and Anacharsis the Scythian) engage in dialogue but, instead of generating philosophical insight, seem to speak past each other, unable to inhabit a culturally alien point of view. Similarly, in his *Symposium* Lucian constructs an ironic counter-image to the myth of philosophy as an ascent to timeless wisdom memorialized by Plato in his own *Symposium*.

While Lucian's parodic treatment of philosophers and their discourse makes him indispensable reading for any student of the history of philosophy, the value of good parody resists summary by its very form, as does a literary repertoire of over 170 characters. Lucian's own philosophical stance is consequently elusive and is never stated directly (even in the *Demonax*). If we consider his *oeuvre* as a whole, however, there are clear patterns of aversion and affinity. Lucian is attracted to Epicureanism for its rational hedonism and critique of religious ideology (see Epicureanism); to Cynics for their courageous practice of *parrhēsia* ('free speech') - the moral basis of satire - and their unflinchingly satiric perspective on the *ancien régime* (see Cynics); to Pyrrhonism for its 'suspension of judgment' on such questions as the value of philosophy as an activity or an institution (see Pyrrhonism). It makes sense, therefore, that Lucian has been of most interest to satirists (for example, Rabelais, Jonson, Swift, Voltaire), sceptics (for example, Hume) and highly literary thinkers of sceptical tendency (for example, Montaigne, Diderot) who do not fit easily into the history of philosophy. Lucian was taken up as a model of the witty, erudite cultural

critic by Renaissance Humanists and is historically significant for transmitting Cynic and Sceptic tradition to Europe (see Humanism, Renaissance §6). David Hume is said to have read Lucian’s comic *Dialogues of the Gods* on his deathbed. In an age as awash in parody, cynicism and religious entrepreneurs as it is alienated from its own traditions, Lucian is finding new audiences.

Lucretius (*c*.94-*c*.55 BC)

Titus Lucretius Carus was a Roman Epicurean philosopher and poet. About his life and personality little can be said with certainty, yet his only known work, 'On the Nature of Things' (De rerum natura), is of considerable size and one of the most brilliant achievements of Latin poetry. A didactic poem in six books, it expounds Epicurean physics. Its manifesto is to abolish the fear of gods and of death by demonstrating that the soul is mortal and the world not governed by gods but by mechanical laws.

The two main biographical sources - St Jerome, and the *Life of Virgil* attributed to Donatus - are unreliable and often inconsistent. The one near-contemporary reference to Lucretius is a letter of Cicero's written in 54 BC, revealing that he and his brother had read and admired the poem. All that we can say with confidence about Lucretius' life is that he lived in the earlier half of the first century BC. He was probably a member of the aristocratic family the Lucretii. Some take the cognomen Carus as testimony that he was a freedman or a slave. However, the dedication of his poem to one Memmius is strong evidence that he was, or aspired to be, a friend of C. Memmius, the wealthy patron of the poets Cinna and Catullus. Much more suspect is Jerome's story of Lucretius' madness caused by a love potion, and of his eventual suicide. Although now rightly rejected, the story was influential in Lucretian criticism, confirming for some the poet's profound pessimism.

The strongest evidence that at Lucretius' death the poem had not received its final revision is V 155, where he makes a promise, nowhere redeemed, of a full treatment of the nature of the gods. Whether other features, such as repeated lines and passages, are also evidence of its unfinished state is more disputed. But since Lucretius states at VI 92-5 that Book VI is to conclude the work, the poem cannot be substantially incomplete.

Lucretius writes as what the Romans called a 'learned poet'. He was a highly educated writer, whose sources of inspiration lay largely in Greek literature. The poem itself belongs to the tradition of didactic poetry, which stemmed from Hesiod's *Works and Days*, although a more direct model is the physical poem of Empedocles, *On Nature* (see Hesiod; Empedocles). He also shows debts to satire, epic and tragedy. Although complaining about the 'poverty' of the Latin language, Lucretius shows skill in adapting existing words to new concepts. His poetical expressions include archaism and periphrasis, but also formal expository devices based on Epicurean methods of argumentation.

The poem is divided into three pairs of books. Books I and II analyse the infinite universe into its microscopic components, atoms and void, refute rival theories of the elements, and show how atoms combine to produce the familiar phenomenal world. The next pair moves up to the human level. Book III covers the soul and its mortality, culminating in an eloquent denunciation of the fear of death. Book IV explains cognitive and other vital functions, ending with a diatribe against sexual passion. Finally, Books V and VI seek to demystify the world as a whole. The former explains its origin and future destruction, its structure and early human history. The latter accounts naturalistically for a comprehensive series of phenomena, from earthquakes to magnets.

In a pair of famous metaphors, Lucretius describes himself as 'traversing the pathless haunts of the Pierides [that is, Muses], where no one's foot has trodden before' (I 921-50), and as planting his feet in the precise tracks which Epicurus has marked for him (III 3-4). In short, he regards himself a faithful Epicurean, but as breaking new ground in his use of poetry. A central question of Lucretian criticism has long been the relationship between poetry and philosophy. It has been doubted whether strict Epicurean philosophy approved of poetry, but the evidence for this is inconclusive at best. Lucretius himself regards his subject matter as off-puttingly obscure, yet essential to human happiness. He therefore compares his use of poetry to the honey which doctors smear on the lip of a cup of bitter medicine in order to trick children into drinking it, for their own greater good. Epicurus is the saviour of mankind, whose philosophy alone can free us from the shackles of religion and from terror at the prospect of death. Both the formal addressee Memmius and the intended wider readership are novices in Epicureanism. Lucretius attracts them in at the beginning with a traditional hymn to Venus, then proceeds to lead them systematically through his arguments about the world's nature and structure. But at the end he confronts them with a disturbing account of the great plague at Athens, which might be regarded as a final test.

Lucretius' poem concentrates on physics, but important ethical statements are made in the proems to several books

and in the concluding parts of Books III, IV and V. He makes many notable contributions to our understanding and appreciation of Epicureanism. For instance, at II 216-93 he offers the only detailed surviving argument for the ‘swerve’ of atoms, which in Epicureanism underpins free will. Book III’s concluding diatribe against the unacknowledged source of most human misery, the fear of death, is especially celebrated. And the history of early human civilization in Book V has been much admired, especially for its reconstructions of the origins of society, language and justice.

In the world of Latin Christianity, Lucretius became the leading voice of Epicureanism, much quoted and vilified as an enemy of religion. He was widely read and studied in the Renaissance, with a tendency to Christianization of his thought (see Renaissance philosophy). He remains a primary source for our knowledge of Epicurean physics.

Łukasiewicz, Jan (1878-1956)

Before 1918, Łukasiewicz's interests centred on logic (in the broad sense) and philosophy, and he worked on induction and probability. He also wrote an important historical book on the principle of contradiction in Aristotle. After 1918, Łukasiewicz concentrated almost entirely on mathematical logic and was the main organizer of the Warsaw School of Logic. The discovery of many-valued systems of logic is perhaps the most important result he achieved. He also invented an ingenious logical symbolism in which brackets (or other punctuation signs) are not necessary (bracket-free or Polish notation). Propositional calculi became a favourite topic of Łukasiewicz's logical investigations. The history of logic was another subject in which Łukasiewicz achieved important results.

1 Life

Jan Łukasiewicz was born on 21 December 1878 in Lwów. In 1896 he began to study law at the University of Lwów, but in the next year he changed his mind and decided to study philosophy under Kazimierz Twardowski. He obtained his Ph.D. on the basis of a thesis on the theory of induction. In 1904-5 he studied in Berlin, with Karl Stumpf, and in Louvain, with the cardinal Mercier. In 1906 he obtained his habilitation degree on the basis of a dissertation on the concept of cause. In the same year he became a *Privatdozent* at the University of Lwów and began courses in logic. His course in 1906 was the first in mathematical logic in Poland. In 1909 Łukasiewicz went to Graz, where he participated in Meinong's seminars (see Meinong, A.). In 1911 he was appointed an extraordinary professor in Lwów. When the University of Warsaw reopened in 1915 (it had been closed by the Tsarist government in the nineteenth century), Łukasiewicz was invited to assume the full professorship there. In 1918 he briefly left to become Minister of Religious Denominations and Public Education in Paderewski's government, but returned in 1920 when the university established a special position for him as professor of philosophy at the Faculty of Mathematics and Science; in fact, it was a position in mathematical logic. As a professor, Łukasiewicz began a very intensive research and teaching programme with the aim of establishing a logical school in Poland. He fully succeeded and, together with Stanislaw Leśniewski and the Warsaw mathematicians (Siperpiński, Mazurkiewicz, Kuratowski), he trained a group of brilliant logicians, including Alfred Tarski (who soon after became the third leader of the Warsaw Logic Group). In the interwar period Łukasiewicz was twice elected the Rector of Warsaw University; he was also awarded an honorary degree by the University of Münster. In 1943-4 he taught in the clandestine University in Warsaw, but he left Poland in 1944 and spent the last months of the Second World War in Germany. In 1946 he became the professor of mathematical logic at the Royal Irish Academy in Dublin, which awarded him an honorary degree in 1955. He died in Dublin on 3 February 1956.

2 Early writings

Induction and probability were the favourite subjects of Łukasiewicz's research in the period 1902-13. At first, he tried to develop the inverse theory of induction proposed by the nineteenth-century logicians Jevons and Sigwart. At the same time, Łukasiewicz was always sceptical about the possibility of evaluating inductive conclusions by probability. He argued that if we have an empirical hypothesis referring to the infinite domain, then its initial (a priori) probability approaches zero and no finite empirical evidence can change this situation. This argument anticipates Popper's basic tenets of anti-inductivism (see Popper, K.R. §2). Łukasiewicz maintained this scepticism about the value of induction in his later writings (1929); he argued that induction had no scientific value, because science is basically deductive and creative.

While working on induction, Łukasiewicz encountered the problem of the logical foundations of probability (1913). In line with his scepticism about induction, he held that probability has no use in the logical evaluation of sentences which are either true or false. On the other hand, formulas with free variables ('indefinite proposition' is his term) can be characterized by their logical probability. Let *D* be a domain consisting of a finite number of objects and let *Fx* be a formula with *x* as a free variable. Assume that *n* is the number of objects in *D* and *m* is the number of those objects which satisfy the formula *Fx*. Under these assumptions, the ratio m/n expresses the probability of *Fx*. The finite case is extensible to infinite domains by means of the mathematical theory of probability.

During this period Łukasiewicz also produced important work on the liar paradox. For Łukasiewicz (1915), the sentence 'This sentence is false' cannot be a value of variables representing sentences. Thus, it does not fall under general logical rules including itself. However, Łukasiewicz did not explain why the sentence cannot be a value of a variable. Tarski carried this out later, developing Łukasiewicz's ideas and arguing that the liar paradox arises because the sentence confuses object-language and metalanguage (see Semantic paradoxes and theories of truth §1).

O zasadzie sprzeczności u Arystotelesa (On the Principle of Contradiction in Aristotle) (1910) is Łukasiewicz's most important work of the period 1902-17. This book has two objectives: a contribution to the history of philosophy by providing an original interpretation of the principle of contradiction in Aristotle, and an evaluation of arguments in its favour (see Aristotle §5). According to Łukasiewicz, we can find three meanings of the principle in Aristotle: first, the logical principle that no proposition and its negation can be true together; second, the ontological principle that no object can have and not have the same property at the same time; and third, the psychological principle that one cannot have contradictory beliefs. Now, the psychological principle of contradiction is plainly false. Since one can prove the equivalence of the logical and ontological principles of contradiction, there remains the problem of providing a justification for one of them; Łukasiewicz argues that Aristotle's justification is not convincing. His main thesis is that we can give a justification for the principle (it follows from the definition of 'being an object'), but that it is not thereby shown to be among the axioms of logic. Hence the reason that we accept it is ethical rather than logical: we need some means of distinguishing truths from falsehoods.

3 Many-valued logic

Łukasiewicz's doubts about the principle of contradiction clearly set him on the path of many-valued logic. Before leaving the university in 1918 for his post in the government, he announced his discovery of a non-Aristotelian logic, then presented the idea in two talks in Lwów in 1920. Łukasiewicz's first motivation for many-valued logic was ethical. He believed that creativity, freedom and responsibility require a special ontology in which determinism fails. For this reason, he introduced a third logical value: possibility, which can be ascribed to sentences about future events. Łukasiewicz was also guided by the ancient question of what truth-value, if any, statements about the future have. However, he soon began to describe his system as 'many-valued logic' instead of 'non-Aristotelian logic'. For it is not clear that Aristotle himself considered the law of the excluded middle to be universally valid; there are statements in Aristotle's writings which suggest that this principle does not apply to sentences about the future. Furthermore, it was Chrysippus, a Stoic, who argued very strongly for the universality of the excluded middle. Thus Łukasiewicz called many-valued logic 'non-Chrysippean' rather than non-Aristotelian. However, on his final view, the issue does not lie in the acceptability of certain principles of logic, the law of contradiction or the law of the excluded middle, for example. Since logic is based on metalogical assumptions, the difference between two-valued and many-valued logic ultimately depends on whether one accepts the principle of bivalence: that every sentence is either true or false.

From the formal point of view, Łukasiewicz first elaborated a three-valued logic. Let the fraction $\frac{1}{2}$ denote the third value. If *p* has this value, its negation not-*p* has the same value. A disjunction always has the value of the 'greater or equal' disjuncts, a conjunction has that of the 'smaller or equal' conjuncts, and an implication has the third value, if its antecedent is 'third' and its consequent false or its antecedent is true and its consequent 'third'; in all other cases an implication is true, except where it has a true antecedent and a false consequent, in which case it is false. So the truth-tables for cases in which only truth and falsity are involved remain the same as usual. Łukasiewicz then generalized many-valued logic to systems with an arbitrary, finite or infinite, number of values. The conditional 'If *p*, then *q*' is true if $p \leq q$, and has a value given by the formula $1 - p + q$ if $p > q$. The value of not-*p* is always calculated as $1 - p$. Łukasiewicz also considered the axiomatization of many-valued logic. For example, he and Wajsberg established that many-valued logic with a countable infinite number of values is axiomatized by the formulas (in Łukasiewicz's notation; see §4 below): *CpCqp*, *CCpqCCqrCpr*, *CCCpqqCCqpq*, *CCCpqCqpCqp*, *CCNpNqCqp*.

Many-valued logic became a basis for Łukasiewicz's treatment of modality. He wanted to have a modal logic with the following principles: (1) if it is not possible that *p*, then not-*p*, (2) if not-*p*, then it is not possible that *p* and (3) for some *p*, it is possible that *p* and it is possible that not-*p* (Aristotle's principle). Łukasiewicz proved that (1)-(3)

cannot be represented together in two-valued logic. Tarski suggested to him that possibility could be defined within three-valued logic by the formula ‘If not-*p*, then *p*’. However, Łukasiewicz did not complete his modal logic before the Second World War. He returned to this question after 1945 and offered several systems of modal logic (see Modal logics §1).

A historical question remains: who discovered many-valued logic? There are anticipations in antiquity and the Middle Ages. One can also find several hints in Peirce’s work and in that of the Russian philosopher Vasiliev. However, it is evident that Łukasiewicz first elaborated many-valued logic as a mature formal system along with its intuitive motivation (see Many-valued logic §1).

4 Propositional calculi

Łukasiewicz invented a special notation for logic. This notation, often called ‘Polish’ notation, ensures that punctuation signs (brackets, dots and so on) are dispensable. The principle is that functors are always written before arguments. For example, the formulas $(p \rightarrowtail \neg p) \rightarrow q$ and $p \rightarrow (\neg p \rightarrow q)$ have respectively ‘*CCpNpq*’ and ‘as their ‘Polish’ counterparts *CpCNpq*’ (‘*C*’ stands for implication, ‘*N*’ for negation). It can be proved that the succession of letters in the Polish notation uniquely determines the structure of expressions.

Łukasiewicz achieved several results in propositional calculi. For example, he axiomatized the classical propositional calculus by the following set of axioms: *CCpqCCqrCpr*, *CCNppp*, *CpCNpq*. He also investigated partial propositional calculi, that is, calculi in which there occur only some of the propositional functors, such as systems with equivalence or implication as sole functors. Giving the most economic axiomatic bases for propositional calculi was his favourite subject-matter. For example, he proved that the sole axiom for the equivalential propositional calculus must have at least ten letters. Łukasiewicz also investigated intuitionistic logic.

5 The history of logic

Łukasiewicz had a deep understanding of the history of logic and proposed a study of it from the point of view of modern mathematical logic. The result was very striking. Łukasiewicz, recognizing that there is a basic difference between the propositional calculus and syllogistic logic which had been overlooked before mathematical logic arose, discovered that the ancient Stoics had elaborated a propositional calculus and thus had a system of logic which differed fundamentally from that of Aristotle (see Logic, ancient §5; Stoicism §10). Łukasiewicz also found interesting examples of propositional logic in the Middle Ages (see Logic, medieval §9). But Aristotle remained Łukasiewicz’s favourite philosopher. Even before 1939 he began research on Aristotelian logic which resulted in an extensive reconstruction of syllogistic logic from the point of view of modern logic. In his book *Aristotle’s Syllogistic from the Standpoint of Modern Formal Logic* (1951) he brought this work together, while displaying his new methodology for the history of logic.

6 Philosophy of logic

Many-valued logic leads to the question of which logic is ‘right’. At first, Łukasiewicz advocated the ontological conception of logic: logic is a description of reality. Hence, one and only one system from the family of rivals is true in the real world. He believed that the infinite many-valued logic is right. However, after 1945 he took a more conventionalist route: logics are devices of our thinking, and when we decide which tool is to be chosen, we must take into account various factors, such as simplicity. Łukasiewicz regarded logic as an independent science which is the servant neither of philosophy nor of mathematics. However, he always maintained that logic is of the utmost significance for philosophy. In particular, he demanded that philosophy should be axiomatized.

Lukács, Georg (1885-1971)

Lukács' Geschichte und Klassenbewusstsein (History and Class Consciousness) (1923) is, for both its intrinsic merits and its enormous influence, the most important work of Marxist philosophy to have appeared in the twentieth century. It sought to render explicit the dependence of Marx's thought on Hegel's dialectic as a means of elucidating both the distinctive character of historical materialism as a form of theoretical inquiry and its revolutionary rejection of the modes of thinking prevailing in capitalist society. Lukács' general aim had been shared by the authors of the first philosophical reflections on Marx's project - Engels and Plekhanov, for example, had stressed its debt to Hegel. Lukács, however, sought to draw Marx into that broad current of twentieth-century Continental thought which has drawn a sharp distinction between the methods of the physical sciences, suitable at best for analysing inanimate nature, and those of the human sciences, whose aim is to interpret human actions in the light of the thoughts which move them. Thus Lukács sees Marx as the theorist, not of the laws of the dialectic or of inevitable social transformation, but of revolutionary subjectivity, of the proletariat as 'the identical subject-object' of history. This was a version of Marxism which suited the times, in the immediate aftermath of the Russian Revolution of October 1917. As the revolutionary tides receded, Lukács found philosophical and political reasons for retreating to a more orthodox historical materialism which laid much greater stress on objective constraints and processes than his version of the early 1920s had. Yet the force of its overall argument and the quality of its individual analyses have made History and Class Consciousness a constant reference-point in subsequent discussions of Marxist theory.

1 Life

Lukács is perhaps the only major Marxist philosopher to have had a significant intellectual career prior to his becoming a Marxist. He later described his youthful views as 'romantic anti-capitalism' - a rejection of existing society based on nostalgia for a past believed to be less fragmented and individualist than the present. The sources of this outlook are no doubt connected to the tensions in Lukács' own background. He was born in Budapest on 13 April 1885, the son of a successful self-made Jewish banker. The predominantly Jewish business class were outsiders in a Hungary still dominated by the gentry, a fact which perhaps helps to explain what Lukács was to call his 'passionate rejection of the order then existing in Hungary', expressed, for example, in an enthusiasm for the revolutionary poetry of Endre Ady. The prime philosophical influences on Lukács were, however, German. He took part in the Heidelberg Circle which Max Weber gathered around him between 1906 and 1918 (see Weber, M. §1). Lukács' pre-Marxist writings, of which the most notable was *Die Theorie des Romans (The Theory of the Novel)* (1916), are permeated by the ideas of members of the circle such as Georg Simmel. They combine a strongly critical attitude towards a modernity conceived as rationalized and soulless with a Neo-Kantian insistence on sharply distinguishing between facts and values, so that authentic values are held to be incapable of achieving practical realization.

Lukács' decision to join the new Hungarian communist party in December 1918 and his participation in its abortive attempt to take power at the beginning of 1919 reflected the belief that this 'tragic' antinomy could after all be overcome, that socialist revolution could bring into being a society which would not suffer from the disharmonies characteristic of modern capitalism. Exiled after the failure of the 1919 Revolution, Lukács was for the rest of his life a leading figure in the international communist movement, indeed he was a party functionary until he took up academic positions after his return to Hungary in 1945.

Controversy, however, dogged his career as a communist. Initially, he was a 'left communist', on the wing of the communist international which demanded an unremitting revolutionary offensive against capitalism. *Geschichte und Klassenbewusstsein (History and Class Consciousness)* (1923), Lukács' masterwork, is arguably still infused with the Messianic hopes which inspired his original adhesion to communism. Its hostile reception in the communist press was, however, one sign of the consolidation of a new 'Leninist' orthodoxy to which Lukács progressively adapted himself. Although *History and Class Consciousness* had an enormous impact on German intellectual life under the Weimar republic (to the extent that Lukács' admirer Lucien Goldmann claimed that Heidegger's *Being and Time* (1927) was, in part, a response), Lukács soon began to distance himself from his book. He always insisted that his reasons for doing so were philosophical (see §3). Certainly, he stuck by the views which he first formulated in the mid-1920s - which involved, in stark contrast to his youthful writings, an

emphasis on the positive virtues of bourgeois civilization and on the continuities between them and those of a socialist society - even when it was politically dangerous to do so. Lukács' participation in Imre Nagy's government during the Hungarian Revolution of 1956 nearly cost him his life. Some commentators, however, believe that, in the very last years before his death on 4 June 1971, Lukács, under the impact of the student revolts in the West and in reaction to the 1968 invasion of Czechoslovakia, was returning to the more revolutionary Marxism of his youth.

2 *History and Class Consciousness*

History and Class Consciousness may be seen as the most powerful philosophical expression of a general revolt against the dominant form of Marxism in the Second International (1889-1914). Antonio Gramsci called the Bolshevik Revolution of October 1917 'The Revolution against *Capital*'; the victory of socialist revolution in a backward country overturned the Marxist orthodoxy formulated by theorists such as Karl Kautsky and Georgii Plekhanov according to which history proceeded by natural necessity according to deterministic economic laws. Both Lukács and Gramsci were influenced by Georges Sorel, for whom revolution was an act of collective will.

However, rather than abandon Marxism as Sorel did, Lukács sought to reformulate it in terms consistent with this conception of revolution. This involved, in the first place, an identification of orthodoxy with method. Marxism could not be equated with any specific theoretical proposition, even the claim that production provides social life with its foundation. Famously Lukács took this to the extreme of asserting that 'if recent research had disproved once and for all every one of Marx's individual theses' (1923: 1), the truth of Marxism itself would be unaffected.

The distinctive feature of the Marxist method, according to Lukács, is that it conceives the different elements of social life, not as isolated fragments, but as aspects of an integrated whole. '*The primacy of the category of totality is the bearer of the principle of revolution in science*' (1923: 27; original emphasis). This assertion is a variation on Hegel's declaration that 'the True is the whole'. Lukács further took from Hegel the idea that it is possible to know the totality only because the subject and object of knowledge are identical: 'consciousness here is not the knowledge of an opposed object but is the self-consciousness of the object' (1923: 178). Therefore, 'reality can only be understood and penetrated as a totality, and only a subject which is itself a totality is capable of this penetration' (1923: 39).

Lukács' appropriation of Hegel provides the basis of the critique of bourgeois thought and society which forms the leitmotif of the central essay in *History and Class Consciousness*, 'Reification and the Consciousness of the Proletariat'. Capitalism is precisely a form of society which operates as if it were not a totality. Taking over and integrating into a Marxist framework the ideas of Weber and Simmel, Lukács depicts a society in which quantity increasingly drives out quality and where instrumental rationality reigns: individual aspects of social life may be modernized and subjected to bureaucratic procedures, but the relationships which bind these together into a whole are incomprehensible. But whereas Weber conceived this process of rationalization as an inescapable consequence of the triumph of modernity, Lukács treats it as a developed form of what Marx in *Capital* calls commodity fetishism (see Marx, K. §10). It is distinctive of capitalism, Marx argues, that social relationships among human beings take on the form of relationships between things. The exchange of commodities on the market rules people's lives, setting a price on their labour power and, in times of economic crisis, perhaps condemning them to unemployment and poverty. Lukács takes over this idea and develops it into the idea of a process of 'reification' permeating the whole of social life. Even the most advanced forms of modern philosophy from Descartes to Kant are scarred by commodity fetishism, and in particular by their inability to grasp society as a whole. Hegel alone recognized that the social totality could only be understood as and by a total subject, but expressed this thought in the mystified form of the concept of Absolute Spirit.

Lukács' solution to what he calls 'the antinomies of bourgeois thought' involved, once again, making strategic use of Marx's *Capital*. Capitalist exploitation depends, according to Marx, on the transformation of labour power, or the ability to work, into a commodity bought and sold for the market. For Marx the chief interest of this state of affairs lies in the way that it makes possible, he believes, the extraction of surplus value from the worker. For Lukács, however, it is of significance chiefly as the limit-point of reification: the workers - that is, the bulk of humanity - are transformed into saleable objects. But, since the exploitation that follows is the presupposition of the entire network of commodity relationships constituting capitalist society, the worker is the pivot of this society. It follows, Lukács believes, that only the working class is in a position to comprehend capitalist society as a

totality. For ‘the worker can only become conscious of his existence in society when he becomes aware of himself as a commodity’. Therefore, ‘his consciousness is *the self-consciousness of the commodity*; or in other words it is the self-knowledge, the self-revelation of the capitalist society founded upon the production and exchange of commodities’ (1923: 168; original emphasis).

The proletariat is thus the total subject required to understand society as a totality, because knowing its own position involves knowing the set of relations of which, as absolute commodity, it is the source. It is, therefore, ‘the identical subject-object of the social and historical processes of evolution’. Further, it is this peculiar status of the working class which makes historical materialism possible. Marx and his successors theoretically articulated the self-understanding of the proletariat. They were able to do so, despite their usually not being workers themselves, because this self-understanding depends on the objective position of the proletariat in capitalist society. There is, in principle, a distinction between the class consciousness that can be imputed to workers on the basis of this position and their actual beliefs and desires. Moreover, the process through which workers become aware of their real situation in society is primarily an intellectual one. None the less, ‘the consciousness of the proletariat must become deed’ (1923: 178). Lukács believes that this is partly because workers becoming self-aware will have practical consequences: ‘*the act of consciousness overthrows the objective form of its object*’ (1923: 178; original emphasis). At the same time, the very process of class struggle in which workers are compelled to engage by their economic circumstances will transform their consciousness. In this way the reified structures of capitalist society will be broken up.

History and Class Consciousness is undeniably a philosophical *tour de force*. Lukács skilfully draws on the resources of German classical idealism and a close reading of Marx’s works to offer a version of Marxism which is, primarily, a theory of revolutionary subjectivity. It is, however, easy to see why later Marxists, such as the Frankfurt School, were more influenced by Lukács’ analysis of reification than by his theory of class consciousness (see Frankfurt School §1). He himself later called the book ‘an attempt to out-Hegel Hegel’, with the proletariat as a sociological version of Absolute Spirit. If this self-criticism is hard to fault, some of the charges made by others seem less fair. The concept of imputed class consciousness, for example, has been seen as an anticipation of Stalinism, since it seems to allow the revolutionary party to tell the working class what the latter ‘objectively’ thinks. In fact, the idea of a party hardly figures in the key ‘Reification’ essay; it appears mainly in the two final chapters of *History and Class Consciousness*, which engage much more directly, and empirically, with historical and social realities than the rest of the book.

3 Lukács as an orthodox communist

For Lukács to come to terms with a communist movement which by the mid-1920s was becoming increasingly Stalinist in any case involved abandoning the main positions of *History and Class Consciousness*. The decisive step in this transition was taken in ‘Moses Hess and the Problem of the Idealist Dialectics’ (1926). Here he defends the later Hegel’s ‘reconciliation with reality’, most famously expressed in the Preface to the *Philosophy of Right* (1821). Lukács praises ‘Hegel’s magnificent realism, his rejection of all utopias, his concern to conceive philosophy *as the conceptual expression of history itself* and not as philosophy *about* history’ (1972: 188), and denounces his left Hegelian critics, such as Hess, for regressing to the subjective idealism of Kant and Fichte. The same stance - an identification with the unfolding historical process, warts and all - informs Lukács’ later philosophical writings, for example, *Der junge Hegel* (*The Young Hegel*) (1948). In Moscow in the late 1920s he was among the first to study Marx’s *Economic and Philosophic Manuscripts of 1844*. This led him to seek to reformulate the dialectic of subject and object at work in *History and Class Consciousness* as the interaction of man and nature, mediated by labour. This forms the leading idea of the posthumously published *Zur Ontologie des gesellschaftlichen Seins* (*Ontology of Social Being*) (1971).

Lukács’ later ‘reconciliation with reality’ involved a strongly positive appraisal of classical bourgeois culture, especially of nineteenth-century literary realism. Indeed Michael Löwy calls ‘Lukács’ political and intellectual career from 1928 onwards… a consistent attempt to "reconcile" Stalinism with bourgeois-democratic culture’ (1979: 204). Certainly there was a marked change from Lukács’ pre-Marxist years, when he had been influenced by Dostoevskii’s novels, works which arguably anticipate many of the formal innovations of modernism. Lukács’ voluminous aesthetic writings from the 1930s onwards wage constant war on the modernism of Joyce and Kafka, which, he argues, marks a regression from the pinnacle of bourgeois cultural achievement, the classical realist

novel. Writers such as Tolstoi and Mann, despite their bourgeois limitations, anticipate the future achievements of socialist realism. Never a time-server (he greeted Solzhenitsyn as a socialist realist novelist). Lukács certainly became a cultural conservative, at odds with Marxist champions of modernism such as Brecht and Adorno. Subsequently, however, Fredric Jameson (1981) sought to develop a version of Lukácsan Marxism in which there is a place for modernism, and even for postmodernism.

ALEX CALLINICOS

List of works

Lukács, G. (1916) *Die Theorie des Romans*, Berlin: Paul Cassirer, 1920; trans. A. Bostock, *The Theory of the Novel*, London: Merlin, 1978.(Lukács' most important pre-Marxist work, expressing what he came to regard as a romantic rebellion against, rather than a materialist critique of capitalism.)

Lukács, G. (1923) *Geschichte und Klassenbewusstsein*, Berlin: Malik-Verlag; trans. R. Livingstone, *History and Class Consciousness*, London: Merlin, 1971.(The most important single work of twentieth-century Marxist philosophy; the English edition contains a highly self-critical preface written in 1967.)

Lukács, G. (1924) *Lenin*, Berlin: Malik-Verlag; trans. N. Jacobs, *Lenin*, London: New Left Books, 1970.(Written immediately after Lenin's death, and offering an interpretation of the unity of his thought around the theme of 'the actuality of the revolution'.)

Lukács, G. (1948) *Der junge Hegel*, Zurich and Vienna: Europa Verlag, 2 vols; trans. R. Livingstone, *The Young Hegel*, London: Merlin, 1975.(A detailed discussion of the development of Hegel's thought up to *The Phenomenology of Spirit* (1807), stressing its sociopolitical content and the theme of labour, and anticipating in many respects the later *Ontology of Social Being*.)

Lukács, G. (1954) *Die Zerstorung der Vernunft*, Berlin: Aufbau-Verlag; trans. P. Palmer, *The Destruction of Reason*, London: Merlin, 1980.(A wide-ranging assault on what Lukács regarded as the German irrationalist tradition culminating in Heidegger.)

Lukács, G. (1957) *Il significato attuale del realismo critico*, Turin: Einaudi; trans. J. Mander and N. Mander, *The Meaning of Contemporary Realism*, London: Merlin, 1963.(A succinct polemical statement of Lukács' views on realism and modernism.)

Lukács, G. (1963) *Die Eigenart des Asthetischen (The Specificity of the Aesthetic)*, Neuwied: Luchterhand, 2 vols. (The magnum opus of Lukács' later years.)

Lukács, G. (1971) *Zur Ontologie des gesellschaftlichen Seins*, Neuwied: Luchterhand; selections trans. D. Fernbach as *The Ontology of Social Being*, London: Merlin, vol.1, *Hegel* (1978), vol. 2, *Marx* (1978), vol. 3, *Labour* (1978).(An attempt to restate the concept of Being starting from an analysis of labour as the mediating activity uniting subject (humankind) and object (nature).)

Lukács, G. (1972) *Political Writings, 1919-1929*, trans. M. McColgan, London: New Left Books.(Includes, along with many more directly political texts reflecting mainly Lukács' 'left communist' period, 'Moses Hess and the Problem of the Idealist Dialectics' (1926), in which he announced his conversion to a more right Hegelian 'realism'.)

Lushi chunqiu

The Lushi chunqiu (Spring and Autumn Annals of Master Lu Buwei), composed 241-238 BC, marks a firm beginning for the eclectic movement in Qin and Han philosophy. It embraces various pre-Qin philosophies such as Lao-Zhuang and Huang-Lao Daoism, Confucianism, Mozi, Legalism, the logicians, the military arts, Agriculturalists, Yang Zhu, Zou Yen and Story Tellers. As a compendium of classical knowledge, the Lushi chunqiu contains cultural and philosophical material on the art of rulership.

The *Lushi chunqiu*, or *Lü-shih Ch'un-ch'iu* (Spring and Autumn Annals of Master Lu Buwei) was completed between 241 and 238 BC by guest scholars at the estate of Lu Buwei during his appointment as Prime Minister of Qin (249-237 BC). It is divided into three sections: the Twelve Chronicles (*shi'erji*), containing twelve subsections with five chapters each and a postscript; the Eight Observations (*balan*), divided into eight subsections of eight chapters each (the first subsection is missing a chapter); and the Six Discussions (*liulun*), divided into six subsections with six chapters apiece. These numbers possibly had symbolic significance, representing the Three Powers, heaven, earth and humans.

The lead chapter of each Chronicle, arranged according to the months of the four seasons, gives instructions on the monthly court ritual, also found in the 'Monthly Commands' chapter of the *Liji (Book of Rites)*. The remaining chapters in each Chronicle discuss numerous concerns of rulership from an eclectic perspective, loosely arranged under a seasonal programme. The spring section contains Yang Zhu and Daoist-like advice on self-cultivation; the summer presents Confucian approaches to education and music; the autumn focuses on military affairs; and the winter focuses on frugal funerals and administering state personnel.

The text is eclectic, and one ought to be wary of scholars who contend that *Lushi chunqiu* as a whole advocates one particular philosophy or argues exclusively against one. Although the postscript claims that the Twelve Chronicles relate the Yellow Emperor's Daoist teachings and the spring Chronicles are Daoist-like, it would be misleading to say that the text is chiefly Daoist because other chapters are clearly Confucian, Mohist and Legalist. Some contend that the text is anti-Legalist; however, the chapter 'Examining the Present' (*chajin*) advocates the Legalist doctrine of not following the standards of the early kings, and some of this material appears in edicts written later by the notorious Legalist Prime Minister of Qin, Li Si. The *Lushi chunqiu* is in fact drawn from various pre-Qin philosophers.

Some of the Daoist ideas in the *Lushi chunqiu* concern the ruler's self-cultivation and ruling by nonaction (*wuwei*) (see Self-cultivation in Chinese philosophy). The ruler practises non-action while the ministers perform their duties. The ruler is warned against overindulgence in sensual gratification, and to carefully guard and protect life; it is the ministers who must sacrifice their lives for the king. The ruler is encouraged to govern with public spiritedness; political factions and selfish exploits are to be avoided. The ruler is expected to be obscure and unknown. His self-cultivation generates harmony with nature, which maintains political order.

The Confucian teachings in the text also deal with the ruler's self-cultivation and rulership. Court ritual and music are emphasized; the *Lushi chunqiu* contains the most extensive extant pre-Qin material on ritual music. Analogies are drawn between musical and political harmony. Following the teachings of Confucius and Mencius, some passages delineate the importance of governing by moral virtue, following the example of the early sage-kings. Other passages resemble the heavy-handed teachings of Xunzi, emphasizing rewards and punishments and the need for the ruler to heed the remonstrance of teachers and ministers.

Mohist ideas are present as well. Many of the chapters, like Mozi, advocate a practical approach to rulership, especially learning from past historical errors. The Mohist material in the *Lushi chunqiu* advocates the value of keeping the people happy and not squandering the state treasury on royal funerals; the latter counters Confucian practice.

The text of Zou Yen and his Five Phases (*wuxing*) philosophy is lost, but passages in the *Lushi chunqiu* represent those teachings. One such passage narrates how past rulers established their respective dynasties by following the cosmic changes of the Five Phases. For example, King Wen founded the Zhou dynasty by complying with the Fire Phase. It further states that water will conquer fire; the King of Qin used this cosmology to justify his unification

of the empire in 221 BC. The *Lushi chunqiu*'s Militarist chapters reject disarmament, and advocate maintaining troops to fight a just war. A virtuous ruler ought to attack an immoral king who oppresses his people.

The *Lushi chunqiu* contains most of the extant pre-Qin Agriculturalist philosophy. Details on farming practices and the importance of bountiful harvests to maintain political order and attract immigrants are discussed. The Agriculturalists, like the Confucian ritualists, emphasize that the ruler should take timely action to create and maintain cosmic and political harmony. Finally, the Story Tellers, the masters of rhetoric, contribute a vast number of interesting, sometimes humorous, illustrative stories to elucidate various philosophical points in the *Lushi chunqiu*. Some of their practical guidelines are applicable to our age. For example, the various discussions on the relationship between humans and nature are relevant to environmental ethics. Some of the ideas on governing and employment of the masses are pertinent to modern politics. The advice given for the ruler's self-cultivation can be applied by anyone.

Luther, Martin (1483-1546)

Martin Luther was an Augustinian monk who found the theology and penitential practices of his times inadequate for overcoming fears about his salvation. He turned first to a theology of humility, whereby confession of one's own utter sinfulness is all that God asks, and then to a theology of justification by faith, in which human beings are seen as incapable of any turning towards God by their own efforts. Without preparation on the part of sinners, God turns to them and destroys their trust in themselves, producing within them trust in his promises made manifest in Jesus Christ. Regarding them in unity with Christ, God treats them as if they had Christ's righteousness: he 'justifies' them. Faith is produced in the sinner by the Word of God concerning Jesus Christ in the Bible, and by the work of the Holy Spirit internally showing the sinner the true subject matter of the Bible. It is not shaped by philosophy, since faith's perspective transcends and overcomes natural reason. Faith, through the working of God's Holy Spirit within the believer, naturally produces good works, but justification is not dependent upon them - they are free expressions of faith in love. Nevertheless, secular government with its laws and coercion is still necessary in this world because there are so few true Christians. Luther's theology brought him into conflict with the Church hierarchy and was instrumental in the instigation of the Reformation, in which the Protestant churches split from Rome.

1 Life

Martin Luther was born in Eisleben, Germany. While studying at the University of Erfurt in 1505, he was nearly struck by lightning in a storm. In terror he vowed to become a monk. Against the advice of friends and family, he entered the local monastery of Observant Augustinians shortly afterwards.

Over the next few years he found himself assailed by doubts as to his salvation and the forgiveness of his sins, which the nominalist theology and penitential practices current at that time did little to assuage. On becoming a Bible professor at Wittenberg in Electoral Saxony in 1512, Luther began to develop his own theological response to these trials through his lectures on the Psalms (1513-15) and on Romans (1515-16), eventually producing a theology of justification by faith (see §§2-3). In the process, he began to criticize the selling of 'indulgences' (reductions of one's punishment and guilt by authority of the Pope), publishing his *Disputatio pro declaratione et vitutis indulgentiarum (Disputation on the Power and Efficacy of Indulgences*, the 'Ninety-five Theses') explaining this disagreement in 1517. Trouble with Rome ensued, and escalated in 1519 when Luther, in a debate in Leipzig, was forced to shift the debate to the issue of papal authority.

In 1520 Luther began working out the implications of his theology. Such works as *Von der Freiheit eines Christenmenschen (The Freedom of a Christian)* and *An den christlichen Adel deutscher Nation (To the Christian Nobility of the German Nation)* outline a programme of reform for the Church. However, the Pope soon threatened him with excommunication, and at the Diet of Worms in 1521 Emperor Charles V confirmed the sentence, forcing Luther into hiding. While there he began work on a German translation of the Bible, a task which was to occupy him until 1534. The Emperor was unable to enforce his edict, however, and Luther was able to return to Wittenberg in 1522.

Meanwhile, others had been pursuing the reformation of the Church, and on his emergence Luther became embroiled in controversy with them. He rejected iconoclastic reform, and later opposed the Peasants' Revolt, in which radical reformers played a key role. His main debate with moderate reformers was over the Eucharist. At Marburg in 1529, attempts to forge a consensus broke down, with Luther sticking fiercely to his belief in the real presence of Jesus Christ in the Lord's Supper. Another significant debate was with Erasmus (§1) over free will, leading to the publication in 1525 of Luther's *De servo arbitrio (The Bondage of the Will)*.

In 1530 Charles V made another attempt to enforce the quashing of the Reformation, but he was not in a position to clamp down on those German princes (the 'Protestants') who refused to carry out his wishes. Luther was left with the freedom to refine and disseminate his theology, pursue controversies, and influence - in Saxony and beyond - those reforms of education, monasticism, the liturgy, preaching and ecclesial organisation in which he had been engaged since 1517. He died while visiting Eisleben in 1546.

2 Theology of humility

Luther was educated in a tradition of voluntaristic theology stemming from William of Ockham (§10) and refined by such thinkers as Gabriel Biel (see Voluntarism). They taught that God in his absolute power has freely ordained a covenant with human beings by which he promises to save those who ‘do what is in them’ (*facere quod in se est*). Biel, for instance, claimed that it is possible for human beings of their own natural powers to love God supremely, at least for an instant, and that God has covenanted to respond to this with his merciful acceptance.

Luther’s earliest theology, in his 1513-15 lectures on the Psalms, retained a *quod in se est* position, albeit one which had been significantly reinterpreted. For Luther, doing *quod in se est* is not a heroic moral achievement, but the acknowledgement of one’s sin, the recognition that one has no power to do good. This self-accusation and confession is the fitting disposition for the reception of God’s grace. God, according to the covenant that he has ordained, will save those who cast themselves upon his mercy in this way, even though they have done nothing which from a human perspective merits salvation ([1513–-15] 1974-6: 267, 373; compare [1515-16] 1972: 135). It was this view which led Luther to begin criticizing the sale of indulgences, which in his view did little to inculcate this humility, perhaps even militating against it (a view found throughout the *Ninety-five Theses*).

3 Justification by faith

From 1515 to 1518 or 1519, catalysed by reading some of Augustine of Hippo’s writings, Luther moved away from the theology of humility and developed an understanding of ‘justification by faith’ which was to remain largely unchanged for the rest of his life (see Augustine §§6, 13). He came to believe that the *quod in se est* position was wrong, and that sinners are passive with respect to their justification ([1525] 1972: 267). That is, the faith to which God responds by saving the sinner is itself a work of God in the sinner, and not the sinner’s achievement. The salvation of some and not others is related not to the fact that some and not others do *quod in se est*, but to God’s ineffable predestination (1517b: thesis 29; [1525] 1972: 292).

Central to this theology is an understanding that human beings are, apart from God’s active grace working in them, not free to choose to fulfil God’s law (1517b: theses 4, 5, 7, 16; 1518: thesis 13). The law which defines righteousness and unrighteousness is not one which could be fulfilled by external obedience; it is a spiritual law which requires a right orientation of the ‘inner person’ ([1522] 1960: 367). It is not that one becomes righteous by performing righteous acts, but that one can only perform truly righteous acts if one has already become righteous (1517b: thesis 40). Since the Fall, when Adam and Eve ate the forbidden fruit in Eden, human beings have been ‘turned in on themselves’ and require God’s intervention to break their self-reliance and turn them to him.

God awakens faith in the sinner by the power of his Word given in the Bible and communicated through preaching, and by the power of his Spirit at work in the sinner (1536a: thesis 28). The Word both condemns, leading sinners to despair of their own righteousness, and inculcates trust in the promises of God made evident in the life of Jesus Christ. In response to this faith that he himself has awoken, God ‘justifies’ the sinner: he refuses to impute sin to the sinner’s account. To put it positively, God decides to impute righteousness to sinners, to treat them as if they were righteous. God does this because of the intercession of his son, Jesus Christ, who in the Incarnation identified himself with sinners, and to whom sinners are joined in faith. Luther speaks of a marriage between sinners and Jesus, with God in his mercy choosing to regard the sinners as participating in Christ’s own righteousness. Faith is both the acceptance of this relationship to Christ and the refusal to attempt to stand outside this relationship when confronted by God (1536a).

In and of itself this justification does not remove actual sin from believers, but leaves them paradoxically ‘at one and the same time righteous and sinners’ - sinners according to what is in them, righteous according to God’s decision. Nevertheless, as he justifies believers, God gives them the gift of the Holy Spirit, who, in a secondary process, works in them to remove actual sin, and to produce righteousness within them by making them conform to Christ. This process is a continual one, and is not finished until the believer is taken into heaven ([1522] 1960: 370).

4 Ethics and politics

Faith is in one sense the fulfilment of the law. Luther called it the fulfilment of the First Commandment, which is to have no other gods before God ([1520a] 1966: 23-4), but stressed that faith itself is not a work but a gift from God. Whatever is done in faith is righteous, because faith by the power of God’s Holy Spirit naturally expresses

itself in love for God and for other people, and naturally works to remove the actual sin remaining in the believer ([1520a] 1966: 27). In this sense the believer is entirely free from all constraints. No law is needed for the believer ([1520a] 1966: 34).

However, true Christians are few and far between in this world, and God has ordained coercive secular government in order to restrain the excesses of sinners. Luther thus claimed that there are two ‘kingdoms’: one of Christians, in which there is complete freedom and love is the basis of action, and to which Jesus’ injunction to ‘turn the other cheek’ is appropriate; and another ‘of the world’, in which justice is the basis of action and punishment is necessary. Luther argued that obedience to secular authority is a necessary service on the part of Christians who value peace, even when that authority is deemed unjust (unless the authority tries to coerce a rejection of faith, in which case resistance in such internal matters is proper) (1523). Spiritual authorities, set up by the community of believers for its own good order, should exercise no secular or coercive power - and Luther thus raged against the peasants when they (to his understanding) tried to coerce spiritual changes in the Peasants’ Revolt of 1525. In his antagonism, he did little justice to their genuine grievances.

Nevertheless, in the absence of an accepted ecclesial authority after the break with Rome, Luther called upon Elector Frederick the Wise - who, although one believer among many, had certain resources - to help in establishing Luther’s reforms of the Church in Saxony. This development paved the way for the later establishment of a State Church.

5 Theological method: philosophy and revelation

According to Luther, philosophy is able to identify and describe things in their worldly relations. It can even partially identify God - as the source of the world’s ordering. Yet it can know nothing of God as gracious and merciful. Philosophy is therefore incompetent to describe anything in its full relationship to God, because God can only be properly identified through his self-identification in Jesus Christ. Even with regard to things in the world, then, philosophy is only partially adequate (see, for example, [1536b] 1960: 137-8).

God’s self-identification is grasped only in faith, since it is a self-identification ‘hidden’ in weakness and suffering. Only by the Holy Spirit’s illumination of the scriptural Word can this revelation be grasped. Faith then construes everything on the basis of the revelation of God in Christ (1518: thesis 20). The perspective of faith is dual, however, incorporating both a Law perspective and a Gospel perspective. The two are dialectically related. Law is the instrument of God’s ‘alien work’, by which he judges and condemns the world, and philosophy can contribute to an understanding of Law. Law is, however, wholly in the service of God’s ‘proper work’, about which philosophy knows nothing, which is to save the world by bringing it to faith and justifying it. God’s proper work is ‘hidden’ within his alien work, and both are shown forth (to the eyes of faith) in the cross of Christ, where God’s saving intention is hidden beneath suffering and condemnation ([1525] 1972: 140).

Only faith in Jesus Christ opens up this true dual perspective of Law and Gospel, which is the complete interpretive perspective for any worldly or spiritual reality, and which incorporates within it those insights of philosophy which it does not destroy. For instance, Luther was happy that Aristotle’s *Logic* should continue to be taught in the universities as long as the inability of syllogistic logic to deal with God’s proper work was acknowledged, but he railed against the use of Aristotle as a foundation for theology, and considered the *Ethics* in particular to be antithetical to the doctrine of justification by faith (1517b: thesis 41).

6 Theological method: biblical interpretation

Rather than philosophy, Luther put biblical exegesis at the heart of his project. In his lectures on the Psalms, he used a complex system which involved a distinction between historical and spiritual interpretation (the former relating the Psalms to ancient Israel and the Jews, the latter viewing them with the eyes of faith, and treating them as prophetic of God’s work in Jesus Christ), and combined that with the medieval scheme of the four senses of Scripture (literal, allegorical = doctrinal, tropological = moral, and anagogical = relating to the end-times). Luther rejected historical interpretation in favour of spiritual interpretation, and agreed with the medieval consensus in privileging the literal sense ([1513-15] 1974-6: 3-5).

As time went on, however, he simplified this system greatly, concentrating on a combined literal-tropological sense and spiritual interpretation, according to which the whole Bible is taken to have as its subject matter Christ’s

work for us, and our response ([1513-15] 1974-6: 402). More precisely, the Bible is both Law and Gospel (the former predominating in the Old Testament, the latter in the New, but both found in each), which correspond respectively to God's alien work of condemnation and humiliation and his proper work of justification ([1520b] 1957: 348). Those with eyes of faith (that is, with the knowledge and experience of what Christ has done for them, conveyed by the Holy Spirit) can see that the message of the whole Bible is that Christ died for sinners; this message is hidden in Law and revealed in Gospel (1521).

Luxemburg, Rosa (1871-1919)

Rosa Luxemburg, of Polish-Jewish origins, was for most of her life a prominent activist and theorist on the radical left of the German Social Democratic Party. She defended revolutionary Marxism against the 'revisionist' critique ofEduard Bernstein; she developed an original and controversial Marxist theory of imperialism; and she advocated direct revolutionary action by the masses, as contrasted with Lenin's insistence on 'democratic centralism' and the leading role of the Party.

1 Beginnings

Rosa Luxemburg was born in Zamość near Lublin in eastern Poland, then part of Russia. Her father was a merchant of Jewish extraction. Two years later the family moved to Warsaw where she spent her childhood. While still at school she engaged in illegal political activities and, in 1889, had to flee to Zurich, where she attended the university. When, shortly afterwards, the Social Democratic Workers Party of Poland was founded, she joined and soon became a leading member. From the beginning, she took the view that, with the emergence of the world market, nationalism had become regressive and dangerously disruptive and that, in particular, the growing integration of the Polish and Russian economies had rendered the demand for Polish independence (advanced by many Polish radicals) redundant. This launched a controversy in which she crossed swords with, among others, Kautsky and Liebknecht. In 1897 she submitted her doctoral dissertation, *Die industrielle Entwicklung Polens (The Industrial Development of Poland)*, still regarded by many as a seminal work. A year later she participated in a marriage of convenience with Gustav Lübeck, a German citizen. This gave her the right to live in Germany and enabled her to take part in the activities of the German Social Democratic Party (SPD).

She lost no time in seizing the opportunity. The 'revisionist' debate was in full spate and, in the summer of 1898, she went to Berlin where she wrote a comprehensive refutation of Bernstein's position (see Bernstein, E.). The result appeared as a series of articles in the *Leipziger Volkszeitung*. In these she argued that transnational cartels, sophisticated credit systems and improved means of communication, far from providing the 'means of adaptation' enabling the capitalist system to soften the impact of economic crises, merely enhanced the system's self-destructive tendencies and hastened the day of its inevitable economic collapse. She agreed that social reforms had a place in the party's programme, but only in so far as they raised the revolutionary consciousness and combat readiness of the working class. Finally, she suggested that Bernstein's basic position was that of philosophical idealism, and that this meant that he had defected to the camp of the reformist *petit bourgeoisie*. It was a case presented with remarkable intellectual acumen. Bernstein himself described her arguments as 'true examples of false dialectics, but handled at the same time with great talent' - a rare compliment. Her collected articles against Bernstein were published as a book, *Sozialreform oder Revolution? (Social Reform or Revolution?)*, in 1899.

In the following years, she consolidated her position in the German socialist movement as a leading theorist and agitator, becoming associated in particular with Kautsky and Franz Mehring. In 1904 she added to her credentials by spending three months in prison for slandering the crown (*Majestätsbeleidigung*); and in the same year, she wrote two substantial articles criticizing Lenin's democratic centralism as applied to party organization (see Lenin, V.I.). In these, as in all her subsequent writings on party organization and tactics, she took a strong stand on a principle Marx and Engels had always insisted upon; namely, that the liberation of the working class can be achieved only by the working class itself. In her view, this meant that the revolution had to be a matter of direct spontaneous action by the workers and that the party as such should act in an enabling rather than in a directing role. 'Historically', she declared, 'the errors committed by a truly revolutionary movement are infinitely more fruitful than the infallibility of the cleverest Central Committee' ([1903/4] 1961: 108).

This view was reinforced when, in 1905, she went to Warsaw to take part in the revolutionary upheavals which followed Russia's defeat in its war with Japan. Her experiences inspired one of her best political works, *Gewerkschaftskamp und Massenstreik (The Mass Strike, The Political Party and The Trade Unions)* (1906). Here she elaborated her 'spontaneity theory' and argued that democratic proletarian organizations are not the precondition of revolutionary action but rather the consequence of it.

2 The analysis of capitalism

Luxemburg's most important contribution to Marxist theory was her *Die Akkumulation des Kapitals (The Accumulation of Capital)*, published in 1913. In it, she pointed out that a capitalist economy can expand only if it can realize surplus value by finding purchasers for the goods it produces. Since the workers in a capitalist economy receive only the value of their labour power, but not the surplus value which they produce, they are unable to repurchase their whole product, thus leaving a surplus product. If the capitalists themselves purchase the surplus product, they gain nothing. No capital is accumulated. The surplus product must therefore find a market beyond the boundaries of capitalism, that is to say, in the non-industrial or pre-capitalist world. Hence the competition for markets in the peasant economies of Asia and Africa, and hence the struggle for political control of those markets - a phenomenon known as imperialism. When, in due course, all non-capitalist areas of the world market have been conquered and absorbed into the capitalist economy, the accumulation of capital will, of necessity, come to a halt and capitalism itself will collapse.

Rosa Luxemburg's analysis carried three important implications. First, it vindicated the claim that the terminal crisis of capitalism was inevitable. Second, it meant that imperialism was, not (as Lenin, for instance, would have it) the 'final stage of capitalism', but a structural feature of capitalism as such. Finally, it meant that war on a worldwide scale between capitalist states was unavoidable.

3 Last years

At the outbreak of war, Luxemburg was among the few who resisted the wave of patriotic war fever which swept the German SPD. In 1916 she was imprisoned and remained so for the rest of the war. Her last significant work, written while she was still in prison and published posthumously, was *Die russische Revolution (The Russian Revolution)* (1922). Once again she voiced her doubts about Lenin's notion of party organization and tactics. His 'Jacobin' style of organization might have been appropriate in the bourgeois revolution, but (she argued) it could not be employed in the very different circumstances of the proletarian revolution. The danger was that the dictatorship of the proletariat could easily be replaced by the dictatorship of a party or clique. For her, the dictatorship of the proletariat implied direct rule by the proletariat and therefore the active participation of the mass of the people. It was, she insisted, no paradox to think of the dictatorship of the proletariat as taking the form of 'unrestricted democracy'.

Upon her release from prison at the end of the war, she joined the leadership of the radical Spartacus group. Following the ill-timed and unsuccessful Spartacist insurrection in 1919, she was arrested and, together with Karl Liebknecht, murdered on her way to prison.

Lyotard, Jean-François (1924-)

Jean-François Lyotard is a prominent French philosopher who is generally considered the leading theorist of postmodernism. His work constitutes an insistent critique of philosophical closure, historical totalization and political dogmatism and a re-evaluation of the nature of ethics, aesthetics and politics after the demise of totalizing metatheories.

In his early works, Lyotard confronts the limitations of dialectical philosophy and structuralist linguistics and analyses the disruptive, extradiscursive force of desire and the nonrepresentational or figurative dimensions of art and literature. In La Condition postmoderne (1979a) (The Postmodern Condition, 1984), he treats narrative pragmatics and language games as the bases for a critical approach to postmodern art and politics, as well as to the problem of justice. Recent texts insist on the obligation of philosophy, politics and writing to bear witness to heterogeneity and to what is repressed or forgotten in all representations of the past. His work questions the limits of philosophy, aesthetics and political theory in terms of problems linked to the irreducible complexities of art and literature and the nonrepresentational affects of historical-political events.

1 Phenomenology, structuralism and the question of art

Jean-François Lyotard was born in Versailles in 1924 and educated in Paris. After passing the 'Agrégation' in philosophy in 1950, he taught for one year in a lycée in Constantine, Algeria, and for seven years in La Flèche, France. He was a member of the radical political group 'Socialism or Barbarism' from 1954 to 1964 and regularly contributed articles to the journal it published and later to *Pouvoir Ouvrier* (*Worker Power*). He has taught at the Sorbonne, at Nanterre, where he played an important role in 'the events of May '68', and at the University of Paris at Vincennes and then Saint-Denis, until his retirement in France in 1987. He was a founding member of the International College of Philosophy in Paris and its second director. He has also been associated with various universities in the United States, including the University of California, San Diego, Johns Hopkins University, Emory University and the University of California, Irvine, where for eight years he was Professor of French and Critical Theory. He has also been a visiting professor in Germany.

Lyotard's first works offer critical perspectives on phenomenology, structuralism, Hegelian dialectics and Marxist political theory. In *La Phénoménologie* (1954) (*Phenomenology*, 1991), which reveals the influence of both Heidegger and Merleau-Ponty on his early thinking, Lyotard analyses phenomenology's radical notion of historicity and the possibilities phenomenology offers for uncovering and moving beyond the limitations of objectivism, subjectivism and idealism.

In *Discours, figure* (1971), phenomenology, Marxism and structuralism are treated as ideological restrictions or deformations of the forces and constructs that underlie ordered reality and thought. Lyotard proposes a deconstructive approach to aesthetics to open the way for new forms of political practice (see Deconstruction). He insists on the radical differences between the linguistic or philosophical determination of meaning and the pictorial, spatial displacement of meaning in painting and experimental forms of poetry. He criticizes philosophy for the way it has attempted to master the sensible by making it discursive or meaningful and thus transform art into a form of philosophy.

Lyotard attacks the structuralist model for language and especially the Lacanian interpretation of Freud as serious restrictions and repressions of desire. He insists on the transgressive effects of desire, whose traces are manifest in the productive-disruptive *force* and not the completed *form* or structure of the figure. The exteriority and resistance of the figural to the discursive are for Lyotard also signs of the resistance of historical-political events to philosophical or historical totalizations. A libidinal aesthetics points to the possibility of a libidinal politics.

Économie libidinale (1974) (*Libidinal Economy*, 1993) attacks the dogmatism of Marxist theory in an attempt to uncover the disruptive traces of libidinal drives that resist being systematized within the dialectic and that are signs of the possibility of alternate forms of political practice. What Lyotard himself calls 'the metaphysics of desire' at the base of his 'libidinal works' produces a humorous and at times outrageous satire of Marx and other political theorists and dramatically indicates the limitations of theory in general and its inability to foster or account for radical, unprogrammed actions or creations.

2 Postmodernism, narratology and critical judgment

In *La Condition postmoderne* (1979a) (*The Postmodern Condition*, 1984), Lyotard defines the postmodern as an era characterized by its incredulity concerning the ability of foundational, totalizing metanarratives - whether liberal or Marxist - to effectively legitimate the sciences and the arts. Lyotard argues that the self-legitimating pragmatics of ‘little narratives’ break with the forms of philosophical and political totalization characteristic of modernism. He defends a concept of language games he derives from Wittgenstein and the principle that the specificity of the rules governing each game must be respected and the different games not confused with or derived from each other. Postmodernism is presented as the basis for a politics rooted in heterogeneity and dissension which ‘would respect both the desire for justice and the desire for the unknown’ (1984: 67).

The central problem posed by Lyotard’s later work is how to create links among the heterogeneous realms and discourses constituting postmodernity without negating their specificity. His innovative readings of Kant bring to light the radical, postmodern implications of Kant’s refusal to derive critical judgment from the cognitive faculty (see Kant, I. §12). Lyotard argues that the form of universalization related to critical (reflective) judgment can never be more than a demand and that Kant’s notion of a universal *sensus communis* does not therefore imply consensus and a predetermined notion of community, as it does for communicational theorists such as Habermas and Rorty, but ‘dissensus’ and an open, conflictual, always undetermined community.

Lyotard argues that the problem of judgment should be considered essential to both the aesthetic and political realms, because it is in them that representation, conceptual knowledge and ethical determination are confronted with their own limitations. The derivation of either realm from any concept or predetermined system constitutes the form of aesthetic and political dogmatism against which Lyotard’s entire critical enterprise is aimed.

3 The *différend* and the unrepresentable in history and memory

In *Le Différend* (1983) (*The Differend*, 1988), Lyotard defines the political in terms of the conflict of fundamental ‘differends’ (disputes), which, unlike forms of litigation that can be judged according to a determined set of rules or laws, cannot be equitably resolved for lack of a universal rule of judgment applicable to all of the arguments. He makes the problem of the linkage between conflicting idioms, phrases and faculties the primary obligation of critical thinking and of a politics rooted in diversity and disputation. To be judicious in terms of differends is to acknowledge the heterogeneity of the discursive universe and the incommensurability of different genres and idioms. It is to bear witness to the injustice occurring whenever ‘a plaintiff is deprived of the means of arguing and by this fact becomes a victim’ (1988: 24).

In *L’Enthousiasme: la critique kantienne de l’histoire (Enthusiasm: The Kantian Critique of History)* (1986a) and *Leçons sur l’analytique du sublime* (1991) (*Lessons on the Analytic of the Sublime*, 1994), Lyotard develops further the postmodern implications of Kant’s *Critique of Judgment* and particularly his concept of the sublime. He argues that the Kantian sublime makes possible a critical approach to history based on the recognition of the limitations of presentation and a respect for the fundamental and irreducible heterogeneity of the sociopolitical realm.

In *The Differend* and other recent works, Lyotard appropriates Adorno’s analysis of the status of art and culture ‘After Auschwitz’ (in *Negative Dialektik*, 1966) and emphasizes what he calls the agony of art and its responsibilities to memory (see Adorno, T. §5). In *Heidegger et ‘les juifs’* (1988a) (*Heidegger and ‘the Jews’*, 1990), which is Lyotard’s contribution to the debate in France over the philosophical and political implications of Heidegger’s relation to National Socialism and of his silence on the subject of the Shoah, Lyotard argues that writing and philosophy have a fundamental obligation both to those who have been excluded from or marginalized in history and to ‘the Forgotten’ or what has not and cannot be represented in thought, history and memory.

It would be possible to connect different texts of Lyotard to the later works of the phenomenologist Merleau-Ponty, to Levinas’s radical reformulation of the ethical, to Adorno’s work on aesthetics and politics, and finally to the work of other contemporary French philosophers such as Deleuze and Derrida. Lyotard’s treatment of the links between aesthetics and politics, his provocative analyses of Marx, Freud, postmodernism and the Kantian notion of the sublime, as well as what Derrida has called ‘the categorical challenge’ he has made to his contemporaries to make the problem of judgment a primary concern (*La Faculté de juger*,1985), all give his work a unique place within contemporary French critical philosophy.

List of works

Lyotard, J.-F. (1954) *La Phénoménologie*, Paris: Presses Universitaires de France, Collection 'Que sais-je?'; trans. B. Beakley, *Phenomenology*, Albany, NY: State University of New York Press, 1991.(A presentation and critical analysis of phenomenology's notion of historicity and its critique of objectivism, subjectivism and idealism.)

Lyotard, J.-F. (1971) *Discours, figure (Discourse, Figure)*, Paris: Klincksieck.(A radical deconstructive approach to aesthetics which criticizes the structuralist model for language and especially the Lacanian interpretation of Freud as serious restrictions and repressions of desire.)

Lyotard, J.-F. (1973a) *Dérive à partir de Marx et Freud*, Paris: Union Générale des Éditions, Collection '10/18'; trans. S. Hanson, A. Knab, R. Lockwood, J. Maierand R. McKeon, *Driftworks*, New York: Semiotext(e), 1984. (The translation contains five chapters from *Dérive* and other essays dealing with Marx, Freud and the politics of the student movement of May '68 that attack the dogmatic, systematic restrictions of different versions of Marxism and psychoanalysis in the name of disruptive libidinal drives and politics.)

Lyotard, J.-F. (1973b) *Des Dispositifs pulsionnels (Mechanisms of the Drives)*, Paris: Union Générale des Éditions, Collection '10/18'.(A collection of essays on art, music, cinema, politics, Adorno and Nietzsche which demonstrate the subversive effects of libidinal politics.)

Lyotard, J.-F. (1974) *Économie libidinale*, Paris: Éditions de Minuit; trans. I. Hamilton Grant, *Libidinal Economy*, London: Athlone, 1993.(A humorous and at times outrageous satire of the dogmatism of Marxist theory which attempts to uncover the disruptive traces of libidinal drives that resist being systematized within the dialectic and that are signs of the possibility of alternate forms of political practice.)

Lyotard, J.-F. (1979a) *La Condition postmoderne: rapport sur le savoir*, Paris: Éditions de Minuit; trans. G. Bennington and B. Massumi, *The Postmodern Condition: A Report on Knowledge*, Minneapolis, MN: University of Minnesota Press.(A critical approach to the conditions of knowledge which defends the self-legitimating pragmatics of 'little narratives' in a postmodern era when the foundational, totalizing metanarratives used to legitimate the sciences and the arts have collapsed and are no longer credible.)

Lyotard, J.-F. with Thébaud, J.-L. (1979b) *Au juste: conversations*, Paris: Christian Bourgois; trans. W. Godzich, *Just Gaming*, Minneapolis, MN: University of Minnesota Press, 1985.(A series of 'conversations' which deal with topics such as pagan philosophy, Plato, Kant and Wittgenstein and stress the fundamental importance of dissension and a critical notion of justice in an era when there exist no universally acknowledged criteria to determine judgment.)

Lyotard, J.-F. (1983) *Le Différend*, Paris: Éditions de Minuit; trans. G. Van Den Abbeele, *The Differend: Phrases in Dispute*, Minneapolis, MN: University of Minnesota Press, 1988.(In this work Lyotard defines the political in terms of the conflict of fundamental 'differends' (disputes), which cannot be equitably resolved for lack of a universal rule of judgment applicable to all of the arguments, and treats the problem of the linkage between conflicting idioms, phrases and faculties as the primary obligation of critical thinking and of a politics rooted in diversity and disputation.)

Lyotard, J.-F. (1985) *La Faculté de juger (The Faculty of Judging)*, with J. Derrida, V. Descombes, G. Kortian, P. Lacoue-Labarthe, and J.-L. Nancy, Paris: Éditions de Minuit; Lacoue-Labarthe's essay trans. as 'Talks', in *The Work of Jean-François Lyotard*, special issue of *Diacritics* 14 (3), 1984.(A collection of essays having to do with Lyotard's work and the problem of judgment which were chosen from papers given at the Cérisy-la-Salle Colloquium on Lyotard of July-August 1982 entitled 'Comment juger?' (How to Judge?).)

Lyotard, J.-F. (1986a) *L'Enthousiasme: la critique kantienne de l'histoire (Enthusiasm: The Kantian Critique of History)*, Paris: Éditions Galilée.(A critical reading of the significance of Kant's notion of the sublime in the *Critique of Judgment* and in his texts on history which propose a notion of politics and justice that cannot be derived from knowledge or any predetermined idea.)

Lyotard, J.-F. (1986b) *Le Postmoderne expliqué aux enfants: correspondance, 1982-1985*, Paris: Éditions Galilée; trans. and ed. J. Pefanis and M. Thomas, *The Postmodern Explained: Correspondence, 1982-1985*, Minneapolis, MN: University of Minnesota Press, 1992.(A collection of short essays in which Lyotard defends his notion of the postmodern in art and politics.)

Lyotard, J.-F. (1988a) *Heidegger et 'les juifs'*, Paris: Éditions Galilée; trans. A.. Michel and M.S. Roberts, *Heidegger and 'the Jews'*, Minneapolis, MN: University of Minnesota Press, 1990.(Lyotard's contribution to the debate in France over the philosophical and political implications of Heidegger's relation to National Socialism and of his silence on the subject of the Shoah in which Lyotard argues that writing and philosophy

have a fundamental obligation to ‘the Forgotten’ or what has not and cannot be represented in thought, history and memory.)

Lyotard, J.-F. (1988b) *Peregrinations: Law, Form, Event*, New York: Columbia University Press.(A series of lectures given at the University of California, Irvine in May 1986 in which Lyotard describes his own intellectual formation and the development of his approach to ethics, politics, art and history. These essays are followed by ‘A Memorial of Marxism’, which analyses his own ‘*différend*’. Includes an excellent bibliography of texts by and about Lyotard compiled by E. Yeghiayan.)

Lyotard, J.-F. (1989a) *La Guerre des Algériens: écrits, 1956-1963 (The Algerians’ War: Writings, 1956-1963),* Paris: Éditions Galilée; 11 of 13 chapters trans. in *Political Writings*, ed. B. Readings, Minneapolis, MN: University of Minnesota Press. (A collection of essays written by Lyotard on the Algerian War for the radical Marxist journal *Socialisme ou barbarie* and preceded by a short preface written in 1989.)

Lyotard, J.-F. (1989b) *The Lyotard Reader*, ed. A. Benjamin, Cambridge, MA: Blackwell.(A representative selection of chapters from Lyotard’s books and other essays on art, literature and politics.)

Lyotard, J.-F. (1991) *Leçons sur l’analytique du sublime*, Paris: Éditions Galilée; trans. E. Rottenberg, *Lessons on the Analytic of the Sublime,* Stanford, CA: Stanford University Press, 1994.(A rigorous analysis of the Analytic of the Sublime in Kant’s *Critique of Judgment* which deals with the limits of presentation in philosophy, art and politics and emphasizes the necessity of reflexive thinking.)

Lyotard, J.-F. (1993a) *Political Writings*, ed. B. Readings, Minneapolis, MN: University of Minnesota Press. (Contains essays from *Tomb of the Intellectual and Other Papers* (1984), *The Algerians’ War* (1989) and recent essays from various sources.)

Lyotard, J.-F. (1993b) *Toward the Postmodern / Lyotard*, ed. R. Harvey and M.S. Roberts, Atlantic Highlands NJ: Humanities Press.(Contains essays from *Dérive à partir de Marx et Freud* and *Des dispositifs pulsionnels,* as well as more recent essays on art and literature.)

Lyotard, J.-F. (1996) *Signé Malraux*, Paris: Grasset.(A biography of André Malraux.)

Lévi-Strauss, Claude (1908-)

Lévi-Strauss is one of the outstanding figures of mid-twentieth century intellectual life, influential far beyond the boundaries of France or the French language, and he has continued to write new work well into his eighties. His name is linked above all to the structuralist movement, of which he has been probably the most single-minded and unwavering exponent, and he was one of the key figures in the experiment of applying the insights of linguistics to the material of the social sciences. Through his work, public recognition of the discipline of anthropology grew dramatically to become an important element in discussion of philosophical issues.

The philosophical environment in France, in which structuralism developed and against which it reacted, was that of Sartrean humanism. In contrast to the existentialist emphasis on individual subjectivity, structuralism expected to find objective solutions to problems in the study of human beings. It was a form of intellectual modernism, a radical break with previous theoretical models and philosophical traditions, symptomatic of post-war optimism for the global applicability of science. It was hostile to metaphysics, bracketed the search for truth and was indifferent to the human subject. And, in contrast to Bergson's emphasis on continuity and flux, structuralism took discontinuity as its founding principle.

1 Life

Claude Lévi-Strauss was born in 1908. His grandfather was the rabbi of Versailles and his father was a painter. After studying philosophy in Paris he went to the new university of São Paulo in 1934 as professor of sociology, and during his five years in Brazil spent some time travelling in the interior. Returning for military service in 1939 he escaped to New York after the fall of France, and spent most of the Second World War lecturing at the New School for Social Research. Two decisive influences on his intellectual development derive from this period: first, contact with Roman Jakobson and second, exposure to the empirical approach of US anthropology. Since then he has lived and worked in Paris, mostly at the Collège de France, and became a member of the Académie française in 1973.

2 The impact of structural linguistics

Attending Jakobson's lectures on linguistics and phonology in 1942 seems to have been a revelation for Lévi-Strauss. Structural linguistics taught him that 'instead of being led astray by a multiplicity of terms, one should consider the simplest and most intelligible relationships uniting them' (1983, ch. 9: 139). The idea that the phoneme has no intrinsic meaning, but only acquires significance in relation to other similar elements, became the heart of his new approach to anthropological debates. The structural study of phonology emphasized two further principles that were to become fundamental to his work: the importance of unconscious mental activity in the production of language, and the fact that language is organized through discontinuous elements linked in particular ways.

Many commentators have linked Lévi-Strauss' structuralism directly to Saussure. However, it is clear from more recent writings that Lévi-Strauss' source of inspiration was Jakobson's interpretation of Saussure. His own use of Saussure was highly selective, emphasizing above all the arbitrary nature of the linguistic sign, the synchronic basis to linguistic analysis, and the syntagmatic and paradigmatic relations that link linguistic signs. These involve relations of contiguity and similarity, analogous to Jakobson's distinction between metonymy and metaphor (see Structuralism in linguistics).

3 The study of kinship

During this same period, Lévi-Strauss engaged in an extensive study of the ethnological literature, seeking to uncover the 'simplest and most intelligible relationships' that united all the wealth and diversity of the ethnographic record. His first area of interest was kin relations, a topic that linked him directly to the central concerns of anthropology and to Durkheim (§3) and Mauss' theories of social solidarity. His first book, *The Elementary Structures of Kinship* (1949), brought these different strands together in a vast synthetic work that transformed the way that anthropologists understood kinship.

Lévi-Strauss proposed that the incest taboo is analogous to the phoneme, in that it has no meaning of its own but

serves to link two domains. This is achieved by the exchange of women between kin-groups, which constitutes the origin of culture and is its ongoing pre-condition. Like all his work, his theory of kinship is controversial, but many of its insights have become canonical.

4 Totemism and *The Savage Mind*

Kinship led Lévi-Strauss to the theme of totemism and systems of classification, and the application of his theories to more obviously mental phenomena. He took issue with the argument, associated particularly with Lucien Lévy-Bruhl, that the thought processes of primitives are based on entirely different principles to our own. In *The Savage Mind* (1962) he showed how all human cultures employ the same principles to define and order their environment. In fact, 'the savage mind' is an unfortunate - if by now well-established - translation of *La pensee sauvage*, since the English expression implies that he is referring to some distinctive primitive mentality. All humans are alike, in his view, in the way that we rely fundamentally on sensual perception for our systems of classification and knowledge - the 'science of the concrete'. At the same time, primitives are just as capable of abstract thought as we are.

However, Lévi-Strauss does specify the significance of different levels of abstraction, expressed through his well-known contrast between the *bricoleur* and the engineer. The French *bricoleur* is a sort of jack of all trades, who puts things together with whatever materials lie to hand. Most of us for most of the time are *bricoleurs*, close to percepts, using the science of the concrete. By contrast, the 'engineer' operates at 'one remove' from observable properties, constructing concepts appropriate for the use to which they will be put.

In practice, Lévi-Strauss has devoted his life's work to studying the thought principles of *bricoleurs* rather than engineers. But implicitly his own work stands as perhaps a key example of what he means by the engineer. He believes that he has identified the abstract principles that underlie all everyday human thought processes, and that anthropology is particularly suited to the attainment of knowledge because it seeks the 'view from afar'. No civilization can think of itself unless it uses others as a basis for comparison. The importance which he attaches to detachment and distance is also at the heart of his critique of Sartre published as the final chapter of *The Savage Mind*.

5 The science of mythology

The most extensive, and probably the best-known, part of Lévi-Strauss' work is dedicated to the understanding of myth, another manifestation of the 'science of the concrete'. While myth uses the material world as means of thought, it is free from the constraints of material reality. Lévi-Strauss contrasts his own approach to myth with that of Jung, who in Lévi-Strauss' view erred by assuming that myths have stable meanings and a referential function. For Lévi-Strauss, the search for the manifest meanings of myths misses their true nature, which lies beneath the multifarious and often fantastic surface phenomena, where the human mind (*l'esprit humain*) rehearses unceasingly the opposition between nature and culture and the contradictions of human life, without offering a clear explanation or meaning.

Lévi-Strauss' approach to the analysis of myths discounts their narrative form in favour of identifying their component parts, in the spirit of the Russian Formalism of his mentor Jakobson, and others such as Vladimir Propp, author of the hugely influential *Morphology of the Russian Folk Tale*. To identify these discontinuous elements Lévi-Srauss in *The View From Afar* coined the concept of the 'mytheme' analogous to the phoneme - 'a purely differential and contentless sign' (1983: 145). These elements are linked by the principles of metaphor and metonymy, of syntagmatic and paradigmatic relations. The language of myths is, then, an unconscious one, rather similar in his view to that of the genetic code: far from being the consciously-created stories of individual narrators, 'myths operate in men's minds without them being aware of the fact' (*The Raw and the Cooked* (1964: 12).

As such, each myth is connected to others, not only within the same language and cultural group, but beyond that to myths recorded for far-away groups speaking different languages. In his four volume *Mythologiques* 1964-71) he traces mythical themes and structures from one end of the American continent to the other. Crucial to this enterprise is the concept of transformation: in Lévi-Strauss' hands this is a relatively static concept, referring typically to the way that myths are related through inversion, that is, the underlying structure of two apparently

divergent and unrelated myths contains the same elements, but arranged in a different way.

His concept of transformation - a formal rather than a dynamic one - typifies his temporal concepts. Synchrony, the suspension of temporal movement, was a guiding principle for structuralism, and for Lévi-Strauss synchrony expresses a core value. Music has provided a significant analogy, for example in *The Raw and the Cooked* where the temporal unfolding of music (and by analogy the narrative unfolding of myths) is subordinate to the structural principles which unite a piece of music, and link it to other pieces.

6 Lévi-Strauss' theory of knowledge

True knowledge for Lévi-Strauss arises from contemplation. In this respect pre-literate societies, where mythical structures are found in their purest form, come closest to his ideal. They typically strive to negate the effects of history and change, in contrast to the modern world where these are celebrated as good in themselves. In many of his writings Lévi-Strauss emphasizes the unity of the human mind across time and culture, stressing the similarity of purpose and method between our distant ancestors who domesticated animals and plants and our own scientific concerns (especially *Structural Anthropology II* (1973, ch.18). In others he implicitly attributes cognitive superiority to the 'engineer' or indeed to the anthropologist. And yet in other respects it is clear that he admires the disappearing world of the primitives who understood the significance of synchrony.

His passionately argued belief that the primitives were as much intellectuals as we are represents a grand if flawed attempt to create a unified theory of the human mind based on detailed comparative work. It derives from a model of human nature which is grounded in intelligence (in contrast to other models which privilege the emotions and instincts, or self-interest and strategy). However for all his intellectualism, many of Lévi-Strauss' ideas have stood the test of time more for their aesthetic insights and intuitions, than for his theoretical elaborations. As a number of commentators have pointed out, the whole elaborate edifice of structural linguistics conceals as much as it elucidates his aims and methods. He is closer to literature, to music, and above all to painting, and in a late work comments that 'the suppression by chance of ten or twenty centuries would not appreciably affect our knowledge of human nature. The only irreplaceable loss would be the works of art' 1993: 176).

In his analysis of actual myths, Lévi-Strauss' rigorous formalism and implicit reductionism is complemented by an extraordinary grasp of empirical detail and a sensitive attention to the distinctive properties - visual, tactile, olfactory, chemical, aural, functional - of whatever it is that the myth purports to be about. This attention to detail partially undermines the importance which he himself attaches to the Saussurean principle of the arbitrariness of the sign. It was clearly an important notion which enabled him to get away from the referential functions of language, but it should not blind us to the fact that most of the mythical signs which he has devoted the last thirty years of his life to analysing are not arbitrary in the Saussurean sense at all.

Mach, Ernst (1838-1916)

Mach was an Austrian physicist and philosopher. Though not one of the great philosophers, he was tremendously influential in the development of 'scientific philosophy' in the late nineteenth and early twentieth centuries. A vigorous opponent of 'metaphysics', he was celebrated as a progenitor of logical positivism. His work is regarded as a limiting case of pure empiricism; he stands between the empiricism of Hume andJ.S. Mill, and that of the Vienna Circle.

Mach's positivist conception of science saw its aims as descriptive and predictive; explanation is downgraded. Scientific laws and theories are economical means of describing phenomena. Theories that refer to unobservable entities - including atomic theory - may impede inquiry. They should be eliminated where possible in favour of theories involving 'direct descriptions' of phenomena. Mach claimed to be a scientist, not a philosopher, but the 'Machian philosophy' was 'neutral monism'. Close to phenomenalism, it saw the world as functionally related complexes of sensations, and aspired to anti-metaphysical neutrality.

1 Life

Born in Moravia, Ernst Mach studied at Vienna, and became professor of mathematics at Graz in 1864. In 1867 he was appointed professor of physics at Prague. From 1895 until 1901 he was professor of history and theory of inductive science at Vienna, before becoming a member of the upper house of the Austrian parliament. Mach's scientific interests were extraordinarily wide. He contributed to acoustics, theory of electricity, hydrodynamics, mechanics, optics, thermodynamics, and the physiology and psychology of perception.

2 Positivism, rejection of metaphysics, thought-economy

Mach was the leading positivist of the later nineteenth century, and the most important progenitor of the Vienna Circle (see Vienna Circle; Logical positivism). Positivism originates with Comte. Central to it is the celebration of scientific knowledge and corresponding hostility to 'metaphysics'; the aim of philosophy is to understand the dominant, scientific mode of thought of the age. Science is seen as descriptive and predictive; scientific knowledge is exclusively of the correlations between phenomena. Comte and Mach differed in the *extent* of their hostility to metaphysics. Comte believed that speculation about the underlying, real nature of things was unwarranted; Mach held that no such nature, the 'things-in-themselves' behind the phenomena, exists.

This rejection separates Mach from 'two-worlds' Kantianism; but he is closer to late nineteenth-century scientific Neo-Kantians who favoured a 'dual aspect' account (see Neo-Kantianism §3). Mach's professed idealist origins (see §4 below), and the labels 'empirio-criticism' and 'critical positivism' bestowed on his position, indicate some affinity to Neo-Kantianism and a corresponding distance from earlier empiricism. Positivism does not imply inductivism, the view that theories are churned out mechanically from the data (see Inductive inference; Mill, J.S. §5). None the less, for Mach all genuine knowledge is scientific knowledge. Although the logical positivists may have rejected merely the transcendental underpinnings of the synthetic a priori, Mach seems to reject it completely, regarding space and time as given, and not as forms of intuition (for which he was criticized by Schlick). Hence there is some truth, but not complete truth, in the traditional view of Mach as the purest empiricist.

Mach's work predated intellectually and for the most part chronologically the 'linguistic turn'. He was innocent of Frege's revolution in logic, central to the outlook of members of the Vienna Circle such as Carnap andReichenbach. Mach's concern with 'analysis' in *Die Analyse der Empfindungen* (*The Analysis of Sensations*) (1886a) was ontological, not the 'logical' or 'conceptual' analysis foundational to analytic philosophy (see §4). Likewise his 'verificationism' was not the developed semantic thesis it became with the Vienna Circle. It was Mach's vigorous hostility to 'metaphysics', more than his detailed views, that was influential.

Central to Mach's philosophy is 'economy of thought', influenced by the economist Emanuel Herrman. Scientific laws and theories are economical descriptions of phenomena. The order science imposes on experience is a biological process of adaptation that overcomes limitations of memory; it does not reflect anything intrinsic to nature. *Die Mechanik in ihrer Entwicklung historisch-critisch dargestellt (The Science of Mechanics)* (1883) is a history of the evolution of science; its origins in 'the manual arts' are emphasized, and false abstraction and 'misplaced rigour' are debunked. 'All so-called axioms are…instinctive knowledge', the funded experience of the

human race. The economy of thought is at the root ofMach's so-called 'sensationalism'. Talk of 'bodies' or 'objects' results from a 'partly instinctive, partly voluntary and conscious economy of mental presentation'.

3 Scientific methodology: laws, theories and explanation

Science, for Mach, is 'the compendious representation of the actual'. Known laws of nature - that is, regularities or interconnections between appearances - are explained and new laws discovered by the construction of theories. Explanation is downgraded, on the grounds that it makes a misguided appeal to metaphysical causes of things. The positivist account of scientific theorizing, with its anti-explanatory bias, is nowadays regarded as moribund. However, as Laudan has argued, Mach's own account of theory is more subtle than is often acknowledged. He was not hostile to the speculative construction of theories, as such. None the less, even if theories are required for the integration of data, they remain *about* the data; given that the correlation of the data takes one beyond them, entities should not be postulated beyond what is strictly necessary for that correlation.

In *Populärwissenschaftliche Vorlesungen (Popular Scientific Lectures)* (1894) Mach distinguishes 'direct' and 'indirect' descriptions. The former involves terms that have acquired 'a fixed significance independent of every object and connexion', taking on 'an "abstract" or "conceptual" import': for example, 'red' or 'straight'. (It has been said that direct descriptions are given in terms of sensations, but Mach is not explicit.) A 'theory' or 'theoretical idea' involves *indirect* description - the extension of analogy - and hence unfamiliar phenomena are made comprehensible. (In talking of 'auxiliary' and 'transitional theories', Mach later implies that there are theories that consist simply in direct descriptions; there is ambiguity here.)

But the picture expressed in an indirect description may impede further inquiry, Mach believes. Black's discovery of specific heat was guided by the picture of thermal processes as the flow of a substance from one body to another; which, however, impeded the realization that heat is produced by friction, for which the picture of heat as a form of motion is more appropriate. Either picture may be heuristically valuable, but neither should be regarded as constituting the reality behind the observable phenomena.

Hence a theory may be heuristically and predictively useful; but the difference between theory and observation is purely quantitative. What is essential is that the theory contain the correct quantitative relations between work done and heat generated, between heat disappearing in one place and appearing in another, etc. Once we have established the functional dependence at the level of appearances, the theoretical model has done its work and should be jettisoned: 'as the new facts grow familiar, [one should] substitute for indirect description *direct* description, which contains nothing that is unessential and restricts itself absolutely to the abstract apprehension of facts'.

Laudan terms this the 'thesis of positivistic elimination'; 'purely observational' and 'mixed theories' (which refer in part to entities beyond the reach of experimentation) should have a different methodological status, and the latter eliminated where practicable in favour of the former. Hence one reason forMach's notorious opposition to atomic theory, namely that it has outlived its usefulness; rather than, as customarily imputed, that atoms are 'unobservable'. In so far as Dalton discovered new connections between phenomena, the theory, properly interpreted as a heuristic device, had been acceptable, Mach believed. Many of Mach's opponents in the atomist debate accepted his methodology and defended atomic theory on its terms.

Mach's deflationary attitude towards theoretical entities is also expressed in his view that theory-choice is underdetermined by empirical evidence. In *Erktenntnis und Irrtum (Knowledge and Error)* (1905) he writes that concepts 'must be consistent with observation and…must be logically consistent with one another. These two requirements are satisfiable in *numerous* ways'. Thus, despite his biological determinism, there is a conventionalist element in Mach's scientific methodology. The pervasive role of the 'economy of thought' implies a more thoroughgoing instrumentalism than forMill, for whom inductive proof was still central (see Conventionalism).

4 Neutral monism

'There is above all *no* Machian philosophy but at most a scientific methodology and a psychology of knowledge…I am by no means a philosopher, but only a scientist' (1905). In one sense, Mach's disclaimer was disingenuous. His philosophical standpoint was one shared with positivists and non-positivists around the turn of the century - namely, neutral monism (a term coined by Russell, though Mach himself referred to both 'monism'

and ‘neutrality’) (see Neutral monism).

The Science of Mechanics introduced a constant theme, leading to the alternative characterization of his position as ‘sensationalism’:

> Sensations are not signs of things; but on the contrary, a thing is a thought-symbol for a compound sensation of relative fixedness. Properly speaking the world is not composed of ‘things’…but of colours, tones, pressures, spaces, times, in short what we ordinarily call individual sensations.
>
> ([1883] 1974: 579)

Mach was greatly influenced by Fechner’s ‘psychophysics’, and worked on the physiological basis of sensation, while opposing Fechner’s mechanistic reduction of mental phenomena to a concourse of physical atoms (see Fechner, G.T. §2). What is required for developing psychophysical investigation, Mach believed, is a *sensational* atomic basis. He aspired to ‘the gathering up of the sciences into a single whole’, but this early version of the ‘unity of science’ was not materialistic. In *The Analysis of Sensations*, Mach traces his idealist roots. In adolescence he was a Kantian, but then he reacted against the thing-in-itself: ‘the world…suddenly appeared to me as one coherent mass of sensations, only more strongly coherent in the ego’. He still shared Berkeley’s belief in an ego not identical with sensations, before finally rejecting that too. Mach concluded that the useful habit of regarding complexes as unities generates the notion ‘at first impressive, but subsequently recognized as monstrous, of a "thing-in-itself", different from its "appearance", and unknowable’. The idea of a transcendental, unknowable Ego is for Mach the last remnant of the detested ‘thing-in-itself’.

Mach emphasizes that the ‘elements’ are neither mental nor physical, subjective nor objective, but ‘neutral’. The title ‘neutral monism’ is therefore more appropriate than ‘sensationalism’, since it implies a rejection of two dualisms, mental-physical and subject-object. The complexes of elements,Mach claims, are functionally interdependent. The green of a leaf is a physical element in its dependence on other properties of the leaf and its environment, and a psychical element in its dependence on my perceptual processes. Which it should be regarded as depends simply on whether one’s interest is that of the physicist or the psychologist.

Mach’s account of the subject prefigures twentieth-century eliminative accounts of the self. But his analysis of objects more strongly anticipates an often complementary phenomenalism. For its originator, J.S. Mill, phenomenalism is the seemingly *non*-neutral view that physical objects are constructions from sensations (see Phenomenalism). Despite protestations of neutrality, doesMach’s view of objects as actual and possible sensations and his rejection of any full-blooded distinction between appearance and reality simply amount to phenomenalism?

Mill’s is the ontological thesis that physical objects are collections of actual and possible sensations, construed as mental, or at least subjective, items. Mach wants to resist this, but claims both that: (1) ‘another’s sensations are no more directly given to me than mine to him’ (1905), yet (2) there is no ‘essential distinction’ between my sensations and those of another person; ‘the same elements are connected at different points of attachment, namely those of the Ego’. (1) implies a subjective interpretation of the elements. Mach recognizes the pressure to go in this direction; but since the ego is, he thinks, a mere thought-economical pseudo-unity, he believes he is entitled to (2), which implies an objective interpretation. His vacillation is understandable but unsatisfactory.

But this ambivalence in neutral monism itself determined the structure of twentieth-century linguistic phenomenalism. Mach was followed by later phenomenalists when he tried to correct Mill’s subjectivism, but he was unable to take Carnap’s further ‘neutralizing’ or anti-metaphysical step of replacing (or perhaps implementing) the ontological thesis with a semantic one - that physical objects are *logical* constructions from sense data (see Carnap, R.). This became possible only after the ‘linguistic turn’ of analytic philosophy.

Neutral monism, then, is the ‘Machian philosophy’. But the scientific methodology was more important, and Mach wrote ten times as much on it as he did on sensationalist epistemology. In another sense,Mach’s disclaimer of any ‘Machian philosophy’ is an important precursor of Carnap’s view of philosophy as the ‘logic of science’.Mach’s attempt to generate a unified science on the basis of ontological neutrality was combined with a circumscribed role for philosophy - the dissolution of ‘pseudoproblems’ - as adjunct to that science. His disclaimer is echoed in Carnap’s positive claim in *Logische Syntax der Sprache (The Logical Syntax of Language)* (1937) that ‘the logic of science takes the place of the inextricable tangle of problems which is known as philosophy’.

Machiavelli, Niccolò (1469-1527)

Florentine diplomat, dramatist and political thinker, Machiavelli's treatise, Il principe (The Prince) (1532a), has earned him notoriety as a political immoralist (or at least an amoralist) and a teacher of evil. In The Prince, Machiavelli posits a complex relationship between ethics and politics that associates princely virtù *with the capacity to know and act within the political world as it 'is', and with the beastly abilities to dispense violence and practise deception. Behind this argument dwells the distinctly Machiavellian insight that politics is a realm of appearances where the practice of moral or Christian virtues often results in a prince's ruin, while knowing 'how not to be good' may result in greater security and wellbeing for both prince and people. Machiavelli warns that the prince's possibilities for success in this matter are always mediated by fortune; hence the prudent prince is one who is prepared to resist fortune by adapting his procedure to the times and his nature to 'the necessity of the case'.*

A less notorious but equally influential text is the Discorsi sopra la prima deca di Tito Livio (Discourses on the First Ten Books of Titus Livy) (1531), in which Machiavelli offers a defence of popular liberty and republican government that takes the ancient republic of Rome as its model and emphasizes the role of the people in the 'public administration' of the city. However, Machiavelli also argues that a republic is only as successful in self-governance as its citizens are infused with civic virtù *and therefore not corrupted. Accordingly, he praises the work of political founders who craft republican laws and institutions, and religious founders who fuse God and* patria *as one in the people's hearts. The apparent tension between Machiavelli's republican sympathies in Discourses and his elitist proclivities in The Prince has helped to fuel a vast interpretive literature concerning his political attitudes, his theory of politics, and the nature and meaning of 'machiavellianism' in Western political thought.*

1 Machiavelli in politics

From the beginning Niccolò Machiavelli's life, like the city of Florence itself, was caught in the ebb and flow of power that characterized the fortunes of the great banking and ruling house of the Florentine Medici. Machiavelli was born into the Florence of Lorenzo the Magnificent, a Medici prince who ruled the city until his death in 1492. When Piero de' Medici fled Florence at the approach of the French army in 1494, the family's hold on power was temporarily broken. After the short-lived regime of the charismatic friar Savonarola, the Florentine republic was restored, and Machiavelli was positioned to begin a career in politics. As Second Chancellor and Secretary to the Ten of War, he worked as a government functionary in affairs of state, travelling widely on diplomatic missions to various secular and ecclesiastical courts, as well as to the campaign headquarters of Cesare Borgia. As a result, Machiavelli became intimately acquainted with the strategies that are a part of 'the art that is necessary to one who commands' ([1532a] 1950: 53).

The Florentine republic was relatively short-lived. With the aid of the Spanish army, the Medici recaptured the city in 1512. Machiavelli was arrested, imprisoned and tortured, under suspicion as a co-conspirator in a plot to assassinate the Medici brothers. In 1513, he was released from prison and sent to rural isolation on his farm in the Tuscan countryside. 'To-day fortunate, tomorrow ruined,' was Machiavelli's succinct summation later. He would never again participate actively in the political affairs of Florence.

Like many displaced political actors, Machiavelli turned to writing. Within the first year of his exile, he produced a short treatise on *l'arte dello stato* wherein, he reported to his friend Francesco Vettori, 'I go as deeply as I can into considerations on this subject, debating what a princedom is, of what kinds they are, how they are gained, how they are kept, why they are lost' ([1498-1527] 1961: 142). Under this seemingly prosaic description smoulders the book that ignited a firestorm of invective in the sixteenth century, a book that continues to be one of the most controversial texts in the history of Western political thought.

2 *Il principe* (The Prince)

In terms of its formal structure, *Il principe (The Prince)* consists of a dedication (to Lorenzo the Magnificent, son of Piero de' Medici), and twenty-six chapters that can be divided into five general sections: chapters I-XI: a typology of states and how they are acquired; chapters XII-XIV: observations on militia and military command;

chapters XV-XIX: advice to a prince regarding character and conduct; chapters XX-XV: advice to a prince regarding circumstances and conditions (fortresses, favours, functionaries and fortune); and chapter XVI: an exhortation to Italy that reconfigures the credo of Pope Julius II: *Fuori i Barbari!* (Put the barbarians out!). The formal structure of the treatise belies its substantive complexity, however, and the magnitude of rival interpretations that attend it. (There are now well over 3,000 commentaries.)

The notoriety of *The Prince* rests primarily upon the nature of Machiavelli's advice concerning the 'methods and rules' that a leader must follow in order to exhibit strength (*virtù*), gain and maintain his position within a particular territory (*lo stato*), and secure the state itself. On these matters, Machiavelli crafts a perspective that aligns politics with warfare, and justifies the deployment of force, the exercise of cruelties, the practice of deceit and the manipulation of appearances in the service of a political mentality that is 'disposed to adapt itself according to the wind' and 'able to do evil if constrained' ([1532a] 1950: 65). In the opening paragraph of chapter XV, in which this perspective on politics crystallizes, Machiavelli dismisses the usefulness of those writers who imagine 'republics and principalities which have never been seen or known to exist in reality', and declares that he will go 'to the real truth of the matter' (*verità effettuale*) ([1532a] 1950: 56). The real truth is that in politics, a ruler must be ready to play upon falsehoods and appearances, 'being often obliged, in order to maintain the state, to act against faith, against charity, against humanity, and against religion' ([1532a] 1950: 65). Accordingly, a prince must 'learn how not to be good,' and 'use this knowledge and not use it, according to the necessity of the case' ([1532a] 1950: 56).

In producing this perspective, *The Prince* forcefully deviates from and craftily subverts an entire genre of Renaissance advice-books that traditionally had aligned princely *virtù* (those qualities that enable a ruler to acquire honour, glory and fame) with the Platonic and Ciceronian 'cardinal' virtues of wisdom, justice, courage and moderation, and with the Christian ethic of goodness and righteousness. Machiavelli's treatise may not have 'revolutionized' the genre of advice-books, as Skinner (1978) contends, but it surely constitutes an unprecedented Renaissance challenge both to moral philosophy and to Christianity as normative bases for a theory of politics. This challenge may have earned the Florentine the admiration of 'anti-philosophers' and 'anti-Christs' of later ages (Nietzsche foremost among them), but more immediately it induced the Roman papacy to place all of Machiavelli's writings on the Index, where they remained for almost 300 years. *The Prince* also set in train its author's long-lived reputation as an atheistic, evil and satanic 'Machiavel', a man 'inspired by the Devil to lead good men to their doom' (Berlin 1982: 35). In contemporary vocabulary, the terms 'machiavellian' and 'machiavellianism' capture an understanding of politics as a domain that embraces naked self-interest, the maintenance of rulership at all costs, the utility of unethical behaviour and the centrality of power as an end that justifies any means.

3 The politics of princes

Despite the durability of these characterizations, Machiavelli posits a more complex relation between value (or ethics) and politics in *The Prince* than either an immoralist, 'teacher of evil', or an amoralist, *realpolitik*, rendering of his views allow. It is true that, unlike any other humanist writer, he openly associates princely *virtù* not with law (which he deems often insufficient to the combat that is ineliminable in politics), but with the abilities to dispense violence, or imitate the lion, and practise deception, or imitate the fox. Behind this argument dwells the distinctively Machiavellian insight that, in matters of state, 'some things which seem virtues would, if followed, lead to one's ruin, and some others which appear vices result in one's greater security and wellbeing' ([1532a] 1950: 57). Goodness is sometimes disastrous in politics, and cruelty less ruinous than clemency. Thus knowledge of beastly abilities and when and how to use them is essential, and it is acquired in two ways: by action, and by the historical study of the good and bad fortunes of 'eminent men'. The men Machiavelli admires and recommends for study are unexcelled in their capacity to exert coercive power and trick others into doing what they want, and thus bring fortune (*fortuna*) under control: the bloody Pope Alexander VI, and the warring and impetuous Pope Julius II, the ruthless Cesare Borgia, the scheming Roman emperor Severus, the more humane Marcus, the wily *condottiere* Francesco Sforza, and Scipio, Cyrus and Alexander the Great.

Yet there are also apparently effective rulers that Machiavelli introduces and condemns: Agathocles the Sicilian, Oliverotto da Fermo, and a host of nefarious Roman emperors. In proffering these examples, *The Prince* appears to formulate a standard of right, or at least prudential, conduct that is appropriate to *virtù*. Thus it throws into

question the standard view that machiavellianism celebrates politics as a sphere of unrestrained evil, and power as the exercise of unremitting violence. Machiavelli's most notable condemnation concerns Agathocles, who arrived at his position as prince in Syracuse through the cold-blooded slaughter of the senators and richest men of the city. Machiavelli remarks: 'it cannot be called virtue to kill one's fellow-citizens, betray one's friends, be without faith, without pity and without religion; by these methods one may indeed gain power but not glory' ([1532a] 1950: 32). The comment on glory (*gloria*) introduces a crucial qualification, because it suggests that the truly *virtù*oso prince is not one who uses his power simply for self-aggrandizement, but in order to construct something that will outlast him, and sanctify his name.

Even in political situations where glorious deeds are unlikely, however, and pure power reigns supreme, Machiavelli distinguishes between ferocious and contemptible conduct, and praises as *virtù*ous those leaders who are feared but not hated. At issue here is a deeper distinction that does not obviate conflict and cruelty as inescapable aspects of political action, but nevertheless differentiates cruelties that are 'well-committed' from those that are 'ill-committed', and therefore increase rather than diminish with time. It is precisely Machiavelli's refusal to disentangle conflict and cruelty from politics that has led some commentators to configure him as a teacher of evil who divorces politics from ethics (Strauss 1958). For others, however, his thought represents a powerful reconstitution of an action concept that, even as it withdraws politics from the domain of purely moral or Christian judgment, reinvests it as a value sphere with its own peculiar and demanding configurations of good and evil, and hence its own norms and standards of ethical evaluation (Berlin 1982).

4 *Virtù* and *fortuna*

Whatever their ethical implications, neither Machiavelli's action concept of politics nor his notion of princely *virtù* can be fully appreciated without considering the role he assigns to *fortuna* in human affairs. The metaphysical picture behind his account of politics is that of an all-pervading necessity that forms the fabric of the world, but wherein freedom, as the exercise of human control over circumstances, is a real possibility at least half of the time. Thus princely *virtù* also presupposes a capacity to master fortune and navigate within the inherent flux and turmoil of political affairs. It is perhaps this elusive capacity that Machiavelli struggled hardest to comprehend, in response to a phenomenological puzzle about action, character, circumstance and method. Strategically, he cast the solution to this problem as the ability to be prudent (*prudente*), and thereby read circumstances, anticipate probabilities and master events. In terms of character, he presented it as the ability to be inherently flexible, the willingness to deviate from what comes naturally and the determination to exercise a steely self-control. Thus, Machiavelli writes: '[the prince] is happy whose mode of procedure accords with the needs of the times, and similarly he is unfortunate whose mode of procedure (*modo di procedere*) is opposed to the times' ([1532a] 1950: 92).

Readers should note, following Pitkin (1984), that Machiavelli's 'metaphysics' is decisively gendered, in so far as he represents *fortuna* not only as a river, but also as a woman, or an engulfing female power that threatens to overwhelm and crush the man of *virtù*. 'Fortune varies and commands men, and holds them under her yoke'; but if the prince is impetuous and willing 'to conquer her by force', he can subdue fortune and thereby use her to his advantage (1498-1527: 99, 94). The symbolic gendering of action, chance and circumstance that Machiavelli effects on a state level in *The Prince* is recapitulated on a domestic level in his play *Mandragola* ([*c*.1518] 1957), where the oppositional erotics of instrumental violence is delivered as comedy. Both *The Prince* as politics, and *Mandragola* as domestics, allow us to see the limits of a world that is constructed as a struggle between *virtù* and *fortuna*, a world wholly devoid of human mutuality, reciprocity and genuine civic life.

5 *Discorsi* (The Discourses)

Discorsi sopra la prima deca di Tito Livio (Discourses on the First Ten Books of Titus Livy) appears to redress, if not repudiate, the uncivic orientation of *The Prince* and its comedic counterpart *Mandragola* by directing its political attentions elsewhere. In this work (probably completed in 1518 although not printed until 1531), Machiavelli distances himself from 'those who generally dedicate their works to some prince' and resolves to undertake the dangerous task of introducing 'new principles and systems' like the explorers of 'unknown seas and continents' in order to 'open a new route, which has not yet been followed by any one'. The new route is discoverable only by way of a return to the past or to 'examples of antiquity' ([1531] 1950: 102-4). Although he implies at the start that the subject matter of his treatise will encompass a vast array of historical and political

topics, *Discourses* in fact concentrates upon one singular historical example, the Roman republic, and one singular type of ruler: 'the sagacious legislator of a republic…whose object is to promote the public good, and not his private interests, and who prefers his country to his own successors' ([1531] 1950: 138). Thus *Discourses* is best read as illuminating the presence of the past, in order to assess what is necessary if modern republics are to flourish and endure like ancient Rome. More indirectly but no less decisively, *Discourses* is also a biting condemnation of the corruption of Florence, a subject that Machiavelli addressed more subtly in *Istorie Fiorentine (The History of Florence)*, a work commissioned in 1520 (although not published until 1532) by a new Medicean court that, at long last, rewarded his literary if not his diplomatic talents.

Discourses is divided into three books (of 60, 33 and 49 chapters respectively) that span an impressive array of political topics concerning the early history of Rome and the Romans: origins and founders, religion, armies, conquests and colonies, the constitution, institutions of government, customs, laws (civil and agrarian), character, warfare and diplomacy, notable leaders (including a tribute to Cincinnatus) and citizens. A careful look at the chapter titles reveals the question that is central to Machiavelli's investigation of Rome: What makes republican regimes stable and enduring? Pocock (1975) argues that in *Discourses* Machiavelli configures the relationship between the all-too-human 'republic' and the unremitting forces of 'time' as a historical confrontation that cannot be deferred. But Machiavelli also attempts to mediate the confrontation through a careful study of the conditions and civic qualities that are necessary if republics are to have even a minimal chance of effectively countering the ordinances of *fortuna* and 'achieving greatness like that of Rome'. Machiavelli's study of civic *virtù* is at the heart of his republican theory of citizenship (see Republicanism §2).

6 The politics of republics

If we approach Machiavelli's classical republican theory as a complex of elements, then four emerge as primary. The first, which can hold for either principalities or republics, is *libertà*, or the condition of being free from subjection to a foreign power and governed by one's own laws. The significance that Machiavelli attaches to liberty cannot be overstated, for he argues that only a city free from servitude is potentially capable of achieving greatness, whether in power, or wealth, or both. For this reason he cautions against attempts to establish republics in countries not suited to them lest the government 'lack proper proportions and have but little durability' ([1531] 1950: 257). Nevertheless and in general, the institutions that are essential to civic liberty are better perfected in republics than in monarchies.

If republics are better safeguards of liberty than monarchies, then republics which entrust their liberty to the people are even more likely to retain freedom than those who favour the nobility. The second element of Machiavellian republicanism involves a defence of the people (*popolo*), as the active guardians of public liberty. As usual, Machiavelli's reasoning on this matter is complex and contextual, and it does not denote an absolute rule. In Sparta and Venice for example, where power was entrusted to the nobility, liberties endured far longer than in Rome. Nevertheless, a republic that desires to extend its empire, rather than merely seek its own preservation, would do well to follow Rome and entrust liberty to the people. A republic that emulates Rome recognizes that its liberty depends upon admitting its people 'to a share of its glory', for the people are superior in maintaining the 'institutions, laws and ordinances' upon which the freedom of the republic rests.

Machiavelli recognizes, however, that a self-governing republic that is animated by ordinary citizens is only as *virtù*ous as its laws and institutions (*ordini*) allow. Thus the third element of his republican theory places great emphasis upon the talents of the founders of republics, like Romulus, and even more emphasis upon those founders who recognize God and religion 'as the most necessary and assured support of any civil society' and use them to divinize the republic's laws and institutions before an awe-struck people, as Numa did in Rome. The welfare of a republic does not consist, then, 'in having a prince who governs it wisely during his lifetime, but in having one who will give it such laws that it will maintain itself even after his death' ([1531] 1950: 146, 148). Among the specific institutions that Machiavelli recommends as most beneficial to republican liberty is a government that combines 'a prince, a nobility and the power of the people' under the same constitution. This was the case in ancient Rome, where the consuls, the senate and the tribunes maintained a tense equilibrium, and kept each other in check. The significance of Machiavelli's advice on this matter has less to do with the later 'separation of powers' doctrine than with his insistence that 'all the laws that are favourable to liberty' result from partisan struggles between the nobility and the people ([1531] 1950: 119).

The emphasis on struggle which, as we have seen, is an indelible aspect of Machiavellian politics, leads to the fourth and most audacious element of Machiavellian republicanism. This element forwards a view of civic participation (*participazione*) as the inevitable clash of interests within and among diverse competing political forces, and it embraces a view of the republic as a 'theatre of turbulence'. From this perspective, the prosperity of republics hinges not upon quelling turbulence or repressing divisiveness, but rather on finding ways of channelling the energies and agitations within the state to good effect. This is particularly true with regard to the people. Accordingly, Machiavelli insists that: 'every free state ought to afford the people the opportunity of giving vent, so to say, to their ambition' ([1531] 1950: 120). Behind this remark rests an even deeper conviction: when civic disturbances generate *ordini* that give the people 'a share in the public administration', they also establish the most assured guardians of liberty, as the tribunes were in Rome.

From the complex of elements (*libertà*, *popolo*, *ordini* and *participazione*) that constitutes the republican orientation of *Discourses* arises a host of secondary issues that are no less important to Machiavelli's analysis of how republics can survive the test of time and fortune. Primary among these is the issue of vulnerability, or what threatens a republic's stability from within and from outside. Since he is well aware of the vulnerability of republics to threats from within, Machiavelli is alert to the problem of corruption (or the disintegration of civic *virtù*), especially as it manifests itself in ambition (*ambizione*) and in factions that threaten to turn productive conflict into internecine warfare (see Corruption §1, 3). Book III, chapter 6 of *Discourses*, 'Of Conspiracies', unmasks the motives and methods that induce individuals, whether alone or in groups, to engage in such warfare, and plot against princes and republics. In true Machiavellian fashion, it also instructs potential conspirators about what works and what does not.

Machiavelli is also aware of the vulnerability of republics to threats from outside, and on this score he repeats and develops an admonition that is found in *The Prince* and elaborated at great length in *Arte della guerra (The Art of War)* (1521): if glory is to be attained, a state must rely upon its own armies and cultivate in its citizens a military *virtù*, as the Romans did. Thus: 'any republic that adopts the military organization and discipline of the Romans…will always and under all circumstances find [her soldiers] to display a courage and dignity similar to that of the Romans' ([1531] 1950: 504). Without good military organization there can be neither 'good laws nor anything else good', and a republic is left prey to the vicissitudes of fortune. Although Machiavelli is in this instance comparing the 'wretched military organization' of Venice to that of Rome, it is hard not to see Florence in this depiction. Read in this light, *Discourses* intones a dirge for Florence, even as it strikes symbols of tribute to ancient Rome.

7 The motives of Machiavelli

Almost inevitably, the comparison of the subject matter of *The Prince* and *Discourses* gives rise to the intriguing question of Machiavelli's motives and his political attitudes. For several centuries, commentators have found it difficult to overlook what seems to be a glaring contrast between the Medicean sympathies of *The Prince*, in which Machiavelli extols princes and insists that all that the people want is not to be oppressed, and the republican convictions of *Discourses*, in which the people are elevated as the guardians of liberty, and the lives of princes are short. In essence, the interpretive question seems to be this: How is it possible to hail Machiavelli as a defender of republican citizenship and liberty, self-government and civic *virtù*, when these appear to be the very regimes and values he teaches his Medici protégé to subvert?

In response, some critics (such as Hans Baron and J.R. Hale) argue that Machiavelli was in fact less a republican and more of a realist who adjusted his advice as political conditions warranted. Thus *The Prince* can be read as a clear-sighted, if opportunistic, attempt to gain favour with the ruling regime. Other critics insist upon Machiavelli's unwavering commitment to republicanism (as Spinoza did), and reconfigure the notorious advice-book as (a) a subversive handbook for republicans (an interpretation favoured by Rousseau); (b) a satire on princely governance (provided by Garrett Mattingly); or (c) a masterful act of political deception, intended for and against the Medici (offered by Mary Dietz). Still others, including Sheldon Wolin, suggest that there are no real dissimilarities between the two texts at all; thus the republicanism of the *Discourses* can be taken as the salutary result of the political acts of a well-advised, *virtù*ous prince. Whatever else, these debates over Machiavelli the man are proof that Machiavelli the theorist of politics sought and perhaps mastered the ability to be simultaneously deceptive and truthful, realistic and ethical, cruel and humane.

MacIntyre, Alasdair (1929-)

Alasdair MacIntyre has contributed to the diverse fields of social, moral and political philosophy. He is one of the leading proponents of a virtue ethical approach in moral philosophy, part of a wider attempt to recover an Aristotelian conception of both morality and politics. His return to ancient sources has been powered by a critical indictment of the modern moral predicament, which MacIntyre regards as theoretically confused and practically fragmented; only a return to a tradition which synthesizes Aristotelian and Augustinian themes will restore rationality and intelligibility to contemporary moral and political life.

MacIntyre's long career culminated in the trilogy of works *After Virtue*, *Whose Justice? Which Rationality?* and *Three Rival Versions of Moral Enquiry*. These works claim that contemporary moral and political philosophy analyses incoherent fragments of a Judaeo-Christian theistic ethic that has lost its point with the increasing secularization of modern culture, leading to practical fragmentation and theoretical incoherence. MacIntyre's aim is to reconstruct a purpose and context for moral thought from the fragments of coherent moral life that survive only in marginal communities alienated from the main currents of the modern world.

This project draws on both philosophy and history. MacIntyre argues that the philosophical justification of rival positions in both theoretical and practical contexts involves narrative explanation. Such narratives set out how competing traditions of inquiry develop from, and are opposed to, each other. A theory is demonstrably superior to another if it explains both the successes and the failures of the previous theory. This form of justification requires an evaluatively engaged historical inquiry, whether applied to scientific theories or moral views.

Underpinning this methodology is MacIntyre's view of rationality and agreement. Rational agreement or disagreement is only possible in the context of a fixed framework of inquiry sharing paradigm uses of concepts and rational procedures. This kind of framework is socially and historically embedded in traditions of inquiry. Thus within or across traditions that can re-interpret each other's terms, rational disagreement is possible. When this is not so, there is interminable disagreement, a failure of rationality, and 'incommensurability'.

MacIntyre's methodology sets the stage for his distinctive history of moral philosophy in the West. Moral life was once rational and unified, in the ancient Greek *polis*, as described in the ethical and political works of Aristotle. This was guaranteed by the relation Aristotle envisaged between his account of human beings as they are, the set of prescriptions directing them as to how to realize their essential nature, and the ideal of human excellence that would be the result (see Aristotle). The discrediting of Aristotle's teleological metaphysics led to the loss of a sense that a human life had a unified purpose which could ground the value of that life. Thus all subsequent moral philosophy in the West is in MacIntyre's view a fruitless search for a means to connect the original elements of Aristotle's tripartite schema, once the idea of the purpose of an individual life has been lost.

This analysis culminates in MacIntyre's apocalyptic account of the contemporary moral situation, which he views as in complete intellectual disorder. The reasons for this disorder are threefold. First, some traditions of thought are just incoherent: they fail to achieve the internal integrity and coherence required in MacIntyre's account of inquiry. Second, even if forms of inquiry are coherent, conflicts among them are pointless since without a matrix of commensurability disagreement across traditions is in principle irresoluble. Third, the contemporary world fails to recognize the intellectual authority of the Neo-Augustinian Catholicism MacIntyre views as uniquely privileged in its relation to other traditions. MacIntyre criticizes contemporary liberalism for vainly aspiring to this role of adjudicating disputes within moral and political culture from a privileged standpoint. Liberalism attempts to regulate this disagreement in the name of higher ideals or privileged procedures, but in MacIntyre's view liberalism has no such intellectual authority over other traditions.

MacIntyre proposes that we resurrect Aristotelian ethics in the modern world. The key element is a new account of the overall purpose of a human life, which permits the restoration of an ethic of virtue, and the cultivation of appropriate forms of community. Politically, MacIntyre is a utopian, seeking the development of small communities analogous to the ancient *polis*, united by a common conception of the good life.

MacIntyre's project has met with a mixed reception in contemporary philosophy; his sharply critical tone, particularly directed against liberalism, has met with robust criticism in its turn. The first line of criticism

challenges the methodological underpinnings of MacIntyre's account: it is argued that MacIntyre has no principled way of distinguishing between the disagreement to which he assigns a positive role within moral traditions and the 'incommensurable' disagreement between traditions he criticizes. In response to this charge MacIntyre has developed a distinctive account of the relation between translation and interpretation, arguing that partial failures of translatability across languages illustrate the type of incommensurability he is concerned with (see Radical translation and radical interpretation).

Second, MacIntyre's account of morality has been accused of being both reductive and foundationalist: we should not see our task in moral philosophy as constrained by MacIntyre's tripartite schema, fitting moral injunctions as a whole to a non-moral foundation in 'human nature'. MacIntyre views the relation between the three elements of the tripartite schema as internally related, unintelligible in isolation; but this internal connection would only be possible in an ideal life. Similarly, MacIntyre's argument does not rest on a prior conception of human nature that constrains possible developments of morality: reflective moral life may be a partial determinant of this 'essence'.

The third criticism is that MacIntyre is actually far more modern than he seems, and rhetoric aside he is as committed to the values of modern moral and political philosophy as any modern liberal. These critics point out that MacIntyre is committed to such values as autonomy and positive freedom, and exaggerates the difference between ancient and modern ethical outlooks.

Their case is strengthened by the final line of criticism, which challenges MacIntyre's historical narrative, and presents an alternative account of the history of moral thought in the West that offers a better explanation than MacIntyre's version. Philosophers such as Charles Larmore and J.B. Schneewind have presented a view of modern moral life more hospitable to the rise of modern liberalism, and Charles Taylor's *Sources of the Self* (1989) offers an alternative view of modern morality far more sympathetic than MacIntyre to the values of the modern world. This third line of criticism is the most powerful since it matches MacIntyre's strengths of combining philosophical insight with wide historical learning.

List of works

MacIntyre, A. (1977) 'Epistemological Crises, Dramatic Narrative, and the Philosophy of Science', *The Monist* 60: 433-72.(An indispensable guide to MacIntyre's early methodology.)

MacIntyre, A. (1981) *After Virtue: A Study in Moral Theory*, London: Duckworth, 2nd edn, with Postscript, 1985. (Clearest statement of the whole project and the account of virtue and the good life. Postscript is a valuable clarification.)

MacIntyre, A. (1984) 'The Relationship of Philosophy to Its Past', in R. Rorty, J.B. Schneewind, Q. Skinner (eds) *Philosophy in History*, Cambridge: Cambridge University Press.(Further methodological reflections on the creative synthesis envisaged between philosophy and history.)

MacIntyre, A. (1985) 'Relativism, Power, and Philosophy', *Proceedings and Addresses of the American Philosophical Association*, Newark, DE: American Philosophical Association, 5-22.(Argues for a principled distinction between the disagreement internal to, and between, traditions. Contests the challenge to this view from Donald Davidson's views on language and translation.)

(1988) *Whose Justice? Which Rationality?*, London: Duckworth.(Extended the scope of the argument from the theory of the good to the theory of practical reasoning. Contains the clearest statement of MacIntyre's criticism of liberalism.)

MacIntyre, A. (1990) *Three Rival Versions of Moral Enquiry*, London: Duckworth.(A return to more methodological reflections, contrasting MacIntyre's methodology with that of post-Enlightenment political rationalism and Nietzschean genealogy.)

References and further reading

Horton, R. and Mendus, S. (1994) *After MacIntyre*, Cambridge: Polity Press.(Multi-author collection of critical essays on MacIntyre's work. Also contains an invaluable reply from MacIntyre clarifying several misunderstandings of his project. Valuable bibliography of MacIntyre's published work.)

Larmore, C. (1987) *Patterns of Moral Complexity*, Cambridge, Cambridge University Press.(Contains an extended discussion of MacIntyre's project, and criticizes both MacIntyre's epistemological foundationalism

and political romanticism. The latter claim should be balanced by a reading of MacIntyre's 'Reply' in the Horton and Mendus volume.)

O'Neill, O. (1989) 'Kant After Virtue', in *Constructions of Reason*, Cambridge: Cambridge University Press.(A criticism of MacIntyre's reading of Kant, typical of corrections of MacIntyre's treatment of individual figures. Also contains a valuable discussion of MacIntyre's attitude to modernity.)

Schneewind, J.B. (1982) 'Virtue, Narrative and Community: MacIntyre and Morality', *Journal of Philosophy* 79: 653-63.(Schneewind's papers are critical but constructive, and suggest the outlines of Schneewind's alternative narrative of the moral philosophy of the modern period.)

Schneewind, J.B. (1983) 'Moral Crisis and the History of Ethics', *Midwest Studies in Philosophy*, 8: 525-39.(See Schneewind (1982) above.)

Taylor, C. (1989) *Sources of the Self*, Cambridge: Cambridge University Press.(A magisterial survey of the historical development of the modern moral identity, indebted to MacIntyre for its general methodology, but very different in its assessment of modern moral philosophy and its resources. An optimistic work which is an essential counterweight to MacIntyre's views.)

Mādhava (d. 1386)

Mādhava was a minister, scholar and philosopher in India in the fourteenth century. He gave support and advice at the founding of the Vijayanagara Empire in southern India, which lasted 300 years. He is best known for his Sarvadarśanasaṃgraha (Survey of the Major Philosophical Systems). In it, he presented sixteen systems of philosophy, starting with the materialists, discussing the Buddhists, Jainas, several Hindu schools and the school of Logic (Nyāya), and ending with Advaita Vedānta. To him and to many scholars at that time, Advaita Vedānta was the most complete and sophisticated philosophy. Mādhava is often identified with other people, especially Vidyāraṇya, the saint and abbot of a monastery in Śṛōgeri. The general view now is that Mādhava may have become a monk, receiving as a religious name that of Vidyāraṇya. This Vidyāraṇya was also an accomplished philosopher. His Pañcadaśī (Fifteen Chapters), a digest of Advaita Vedānta, is still popular today.

1 Mādhava and his times

Mādhava was a statesman, philosopher and polyhistor who lived in southwest India in the fourteenth century. Four names are associated with this one person. After examination of the various hypotheses regarding these names, the most frequent solution seems to be to regard two of them, Mādhava and Vidyāraṇya, as the civil and religious names respectively of the same person, and to treat Bhāratītīrtha as the name of his teacher and Sāyaṇa as the name of his brother. This opinion ignores the indigenous tradition.

By the fourteenth century, the Muslims were well settled in the north of India and were making almost continuous efforts to occupy the south as well. The Vijayanagara empire, founded by the brother kings Bukka I and Harihara I in the fourteenth century, resisted the invasions for a long time, flourishing until the middle of the seventeenth century. It was based in a region south of the rivers Krishna and Tungabhadra. At that time the empire was a bastion of the best of Hindu culture, the intellectual strength and growth of which was reflected in architecture, a variety of arts, and learning.

Mādhava was one of the primary instigators of this cultural tradition. He spent part of his life at the court as an advisor to the brother kings. It is speculated that he may have left to become a monk at the monastery in Śṛōgeri ('The Mountain Peak'), a few miles south of the capital, Vijayanagara ('The Victorious City'). When he entered the monastery, he received the religious name Vidyāraṇya ('The Forest of Wisdom or Knowledge'). Adding a religious name to a civil one was unusual.

Traditional Indian sources do not identify the two personages. On the contrary, they insist on their difference. The abbots at Śṛōgeri entered the monastery as celibate young men. It would be exceptional that a mature person like Mādhava, who had spent his life engaged in worldly affairs, should later have become an abbot.

2 Mādhava's works

The ascription 'Mādhavīya' ('of Madhava') occurs in the titles of a number of works. We know from inscriptions that grants were given to learned men (pandits) to help produce commentaries on the Vedic tradition. Mādhava, acting at his kings' behest to propagate the Hindu tradition, appointed several capable scholars to produce works, such as commentaries on the Vedas. Among them was Sāyaṇa, who seems to have been a leader of a writing guild. Mādhava was the mastermind and 'purse' behind this voluminous body of work. His name lent authority, and he himself could also have contributed to these works. It is virtually impossible to determine their exact authorship or date.

Because of the uncertainty of authorship, it is also difficult to make a definitive list of works. It is possible that Mādhava co-authored chapters or even whole works. In the case of the *Sarvadarśanasaṃgraha (Survey of the Major Philosophical Systems)*, he may have shared a chapter with his brother, Sāyaṇa. Of the several works that are ascribed to Vidyāraṇya, the *Pañcadaśī (Fifteen Chapters)* may have been written by, or at least in collaboration with, Vidyāraṇya's teacher, the abbot Bhāratītīrtha. The *Jīvanmuktiviveka (Correct Insight into the Concept of Liberation-while-Alive)* is attributed to Vidyāraṇya.

Of some thirty works that are ascribed to Mādhava, Vidyāraṇya, Sāyaṇa and Bhāratītīrtha, several are still only in manuscript form. A number were edited either in part or in full in the nineteenth century and at the beginning of

the twentieth century. Some were translated into various Indian languages and several also exist in English today.

Some of the best-known works that have proved to be important for the development and preservation of the Hindu tradition are the *Sarvadarśanasaṃgraha*, the *Jīvanmuktiviveka*, the *Pañcadaśī* and the *Vivaraṇaprameyasaṃgraha (Compendium of Objects of Knowledge in the Vivaraṇa Tradition)*, to mention just a few. In the *Sarvadarśanasaṃgraha*, the author discusses sixteen philosophical systems, which he arranges according to their relation (or lack of it) with Vedānta philosophy. He starts with the materialists, who are the most alien to Vedānta, and ends with the Vedānta teaching. The materialists praise immediate enjoyment and have no appreciation for spiritual striving and growth, whereas Vedānta aims at spiritual accomplishment, with its final goal of liberation from repeated physical existences. Between these two systems, he presents, among others, those of the Buddhists, the Jainas and the Naiyāyikas (Logicians). The author shows himself here as an erudite scholar of philosophy, skilled in logic.

The *Jīvanmuktiviveka* deals with the state of being-liberated-while-still-alive. It is well known that the Buddha attained such a state of enlightenment and continued to teach for almost five more decades before he died. The idea that it is not only possible, but quite likely that a person will live for a long time after attaining full enlightenment is explained here. In this state, a person still functions normally, but is not subject to the usual desires and passions, and does not accumulate karmic impressions - either good or bad - that will result in future rebirth. After gaining the insightful experience, the person still lives on, just as a potter's wheel keeps turning even though the pot is already completed. The author supports his statements with a number of quotations from the most essential sources of Hindu ideology: the *Bhagavad Gītā*, the Upaniṣads, the *Yogasūtra*, and so on. Many consider this work highly eclectic.

The *Pañcadaśī* presents in an accessible manner the main teachings of Vedānta and is still well liked and much revered. It is divided into three sections consisting of five chapters each. The first set deals with correct insight (*viveka*) leading to knowledge of reality, the second with consciousness which illuminates, and the third with the bliss experienced in the state of trance.

Vidyāraṇya's *Vivaraṇaprameyasaṃgraha* is a work of the greatest importance to Advaita dialectics. Vidyāraṇya shows himself here as an erudite philosopher arguing against his opponents' views. Although his is considered a commentary on Prakāśātman's commentary on Padmapāda's work, each of these is not a commentary as such, but rather an expansion and elaboration of the previous work in the same *vivaraṇa* ('laying out bare' - in other words, 'analysis') tradition of Vedānta. Padmapāda is considered the father of the Vivaraṇa school. His exposition is based on the first four sections of Śaōkara's *Brahmasūtrabhāṣya*.

Vidyāraṇya's *Vivaraṇaprameyasaṃgraha* deals with the method by which it is possible to examine true objects and distinguish between empirical and philosophical knowledge. In order to make these distinctions, it is essential that the objects of knowledge (*prameya*) be properly established. Vidyāraṇya was also a philosopher of language and had particular interpretations of traditional terms in Vedānta. He departed from the usual Vedāntic understanding of concepts such as self (*ātman*); according to him, Vedānta does not teach that the self continues to exist after the death of the physical body.

3 Advaita Vedānta refined and restated

Although many of these works show a thorough knowledge of all the schools of Indian philosophy, their primary focus is on the nondualist Vedānta of Śaōkara. This philosophy was concerned with finding the true nature of reality, and liberation. In general, medieval Indian thinkers did not aim at originality and innovation. Only those with strong minds and personalities changed the course of the teachings, giving rise to new varieties of Vedānta, such as the dualist school (see Vedānta §3). We tend to single out these thinkers and teachers, whereas we often do not know the names of those who stayed in the fold of the old tradition. We know of Mādhava and Vidyāraṇya because of their significant activities besides teaching Śaōkara's Vedānta. Mādhava, for instance, is notable for his well-rounded knowledge and active life as a statesman. Although they did not necessarily formulate original thoughts, Mādhava, Vidyāraṇya and numerous others contributed to keeping alive the Vedānta tradition by restating and refining it. Mādhava's activities helped to preserve the Hindu traditions by building a cultural and political stronghold against attacks and foreign influences.

Madhva (1238?-1317?)

Madhva, Hindu theologian and ascetic, founded the philosophical school commonly called Dvaita Vedānta, but which Madhva and his followers termed tattvavāda*, or realism. The name Dvaita refers to Madhva's dualistic interpretation of the Hindu canonical texts known as the Upaniṣads, also known as Vedānta. In contrast to the monist and semi-monist systems of his two major Vedāntin predecessors, Śaōkara and Rāmānuja, Madhva asserted the absolute difference between God (*īśvara*) and human souls (*jīva*), claiming that they were uncreated, eternal principles with fundamentally distinct natures. Madhva delineated the respective natures of God and souls so as to assert God's complete transcendence of the world and to legitimate the practice of devotion as the principal means of attaining liberation from the cycle of rebirth (*saṃsāra*). Madhva's realist epistemology served as the foundation for this ontological emphasis on difference (*bheda*).*

Our knowledge of Madhva's life comes from hagiographical literature and from scattered references to personal experience in his works. While traditions differ regarding his dates, inscriptional evidence corroborated with statements by Madhva make the dates 1238-1317 most likely. Madhva was born near Udupi in the present-day Indian state of Karnataka, where he established a monastic compound which continues to function as the ritual centre of modern Mādhvaism. Madhva presented himself as an incarnation of the Hindu god Vāyu who would save humankind through correct knowledge. This unique claim for a Hindu thinker has prompted some scholars to speculate that Madhva was influenced by Christianity. In fact, Madhva's milieu was heavily Jaina and his epistemology and ontology arguably reflect this influence.

Madhva's emphasis on the ontological significance of difference and its counterpart, individuality, was supported by his realist epistemology, which asserted the inherent validity of experience wherein difference is presented as an undeniable fact. Madhva used this ontological framework to support his sectarian devotion to the Hindu god Viṣṇu and articulated in many of his writings those unique qualities which, he believed, render Viṣṇu superior to all other Hindu gods.

Madhva's emphasis on the ontological significance of difference (*bheda*) was a direct challenge to his famous predecessor Śaōkara, a monist who claimed that the individual human soul was completely identical with the Godhead at the level of ultimate truth. By contrast, Madhva divided reality into two separate, uncreated principles, God (*īśvara*) and matter (*prakṛti*), and further subdivided matter into sentient matter, or souls (*jīva*), and insentient matter (*jaḍa*). Differences exist between these three categories and between individual members of the same category, resulting in a fivefold schema of difference: souls-God, souls-souls, souls-insentient matter, insentient matter-insentient matter, insentient matter-God; God cannot differ from himself. According to this view, no two things are identical, although their difference might be extremely subtle. Madhva rejected the Nyāya-Vaiśeṣika position on universals (*sāmānya*), arguing that universalized conceptions ultimately rest on perceived similarities (*sādṛśya*) between particular objects (see Universals, Indian theories of §2).

Madhva saw this particularity as resulting from the fact that qualities are completely identical with their substances. However, Madhva wanted to avoid taking the Buddhist position, which states that since all entities are nothing more than their qualities, they are impermanent and inessential. To distinguish between qualities and substances while upholding the notion that qualities are essential to the substance, Madhva posited the concept of *viśeṣa*, often translated as distinction. In Madhva's system, these distinctions exist between the entity and its attributes in such a way that the attributes are nevertheless integrated into the entity. Thus, the concept of *viśeṣa* allows an entity to possess different, often changing attributes without compromising the object's inherent unity or ontological validity. This challenging doctrine engaged many of Madhva's commentators.

Viśeṣas play an important role in the relationship between God and the world. One of God's permanent attributes is his independence (*svatantratva*), whereas souls and insentient matter are permanently dependent (*paratantra*) upon God. While insentient matter is beginningless, God transforms it from an original chaos into an ordered reality, and finally returns it to its original form. God, however, remains unaffected due to his transcendence.

Souls, although eternal in nature and generally free in agency, depend upon God for their destinies, since God governs the law of karma and grants liberation through grace. While the recognition of one's dependence upon

God inspires one to acts of devotion (*bhakti*) which can lead to liberation, ignorance can lead to eternal damnation. Fatalistically, Madhva asserted that a given soul's capacity to recognize its dependence upon God was a result of its permanent attributes and thus predetermined. In accordance with the three traditional Hindu locales for rebirth, Madhva asserted a threefold gradation of souls: those destined for eternal liberation, those destined for eternal *saṃsāra*, and those damned to eternal hell. While God oversees this structure, he is not implicated in its apparent injustices, since it is the souls' inherent properties which bring these about. God merely metes out destinies in accordance with behaviour. Thus Madhva maintained God's supremacy both by removing him from the presence of evil and placing him in charge of retribution.

The most crucial element of Madhva's epistemology was the role he gave to the 'witnessing subject' (*sākṣin*), which coordinates the senses and illuminates their data. Madhva posited the *sākṣin* as infallible and able to pass final judgment on the validity of the data presented to it, thereby asserting the self-validation of experiential knowledge. Indeed, while Madhva advocated three means of knowledge (*pramāṇas*) - perception, inference and verbal testimony (especially sacred scripture) - he insisted that the latter two *pramāṇas* never be so construed as to contradict perception. This position was one of his principal attacks upon the Advaitins, who looked to statements in the sacred texts declaring the identity of the soul with God as proof of the unreality of ordinary experience. However, Madhva fiercely defended the sanctity of the revealed literature (Veda) due to its ability to grant access to privileged domains of knowledge such as the nature of duty (*dharma*) and liberation (*mokṣa*).

Mahāvīra (6th-5th century BC)

Mahāvīra's significance for Jaina philosophy is comparable to that of his contemporary, Buddha, for Buddhist philosophy. Both are regarded as the source of ideas, concepts and categories with far-reaching implications for later philosophical activity. In their respective traditions, both Mahāvīra and Buddha are recognized as enlightened or omniscient beings because they grasped the essential nature of reality, human life and the world. The teachings ascribed to them were at first passed on orally and were compiled into their present form several centuries later.

Despite similarities between Mahāvīra and Buddha, both in their biographies and in their rules for ascetics, Jainism is clearly an independent stream which has made its own valuable contribution to the development of Indian philosophy. One significant difference between Buddha and Mahāvīra is that Mahāvīra was not the founder of a new movement, but rather a reformer of the teachings of his predecessor, Pārśva.

'Mahāvīra' (literally 'Great Hero') is an epithet used especially for the Jaina saviour Vardhamāna. His dates are a matter of considerable debate, partly because they are related to those of the Buddha's, which are also problematic; neither wrote any works, which otherwise might have helped with deciding their dates. According to the Śvetāmbara sect of Jainism, Mahāvīra died at the age of seventy-two in 527 BC, whereas the Digambara sect gives the date as 510 BC, and recent research suggests 477 BC. The source of Mahāvīra's teachings is a body of scripture which was redacted in its present canonical form by a council held in Valabhī, Gujarat, around the fifth century AD. The Digambara sect rejects this Śvetāmbara version, believing the original canon to have been irretrievably lost, although it does have texts regarded as procanonically sacred. The style of both sets of texts is very repetitive, and whatever has a direct bearing on philosophy has to be extracted from a huge volume of material on a wide range of other themes, such as the religious practices of ascetics and the conduct of monks and nuns. The teachings are generally in the form of questions put by disciples and answers given by Mahāvīra or one who has heard his teaching, with little, if any, philosophical discussion of the concepts.

The authority which Mahāvīra's teaching enjoys in the Jaina tradition is inextricably related to the position given to him and twenty-three others as universal teachers. Historicity is ascribed only to the last two, Pārśva and Mahāvīra. All have the epithet 'Jina', meaning 'Victor' or 'Conqueror' of the passions fettering an individual. The tradition acknowledges them as omniscient beings who have obtained enlightenment through extreme asceticism. Their teachings are like a ford that enables others to cross to the other side of human existence, and hence they are called 'Tīrthaṃkaras', 'Fordmakers'.

Mahāvīra's teaching and biography represent an ascetic (*śramaṇa*) tradition that was already well established during his lifetime, one to which even his predecessor Pārśva belonged 250 years earlier. The exact origins of Indian asceticism are difficult to trace, but it is possible that there were world-renouncers before the arrival of the Aryans around 1700 BC. Mahāvīra's teaching characterizes this ascetic tradition in that he too holds that life in the world intrinsically entails suffering, ignorance and pain, which may be overcome through the knowledge of reality and of one's essential nature that is attainable in an ascetic life. This basic teaching is associated with the theory of karma, whereby karma is responsible for the cycles of existence (*saṃsāra*) that living beings have to undergo until they realize how, through Mahāvīra's teachings, accumulated karma may be destroyed and future ones avoided. In its simplest form, the theory, as it applies to human beings, is presented through an agricultural metaphor: one's actions, including thoughts and words, are said to leave behind traces which, like seeds, bear fruit in an appropriate environment either in one's present existence or a future one, the former being also determined by previous karma. This theory, shared by Buddha and the Upaniṣad thinkers, is the hallmark and essential starting point of all soteriological Indian systems and seems to have been pan-Indian during Mahāvīra's time, which is perhaps why no philosophical justification is offered for its acceptance in his teachings (see Karma and rebirth, Indian conceptions of).

Mahāvīra's interpretation of karma is unique, in that it is seen as particles of subtle matter which attach themselves to the soul, hindering the development of what later thinkers called the three jewels of Jainism, namely the soul's innate powers of right belief, right knowledge and right conduct. Mahāvīra mentions killing or violence (*hiṃsā*) as the cause of karma and says that the practice of nonviolence (*ahiṃsā*) is the common doctrine of all Jaina

fordmakers: ‘The Arhats and Bhagavats of the past, present, and future, all say thus, speak thus, declare thus, explain thus: all breathing, existing, living, sentient creatures should not be slain, nor treated with violence, nor tormented, nor driven away.’

It was not until around the fourth century AD that Mahāvīra’s metaphysics, epistemology, ethics and cosmology, unsystematically scattered around in the various canonical works, were presented in a manner comparable to the basic philosophical texts of the Hindu systems. This was done by Umāsvāti (also called Umāsvāmī) in his *Tattvārthasūtra*.

Maimon, Salomon (1753/4-1800)

Educated as a rabbi in Lithuania, Shlomo (Salomon) ben Yehoshua migrated to Germany and adopted the surname Maimon in honour of Maimonides. His criticism of Kant's dualism and his monistic account of the human mind as an imperfect expression of God's infinite mind influenced Fichte, Schelling and Hegel. Kant regarded him as the critic who understood him best.

Maimon's system combines rational dogmatism with empirical scepticism. As a rational dogmatist, he argues that cognition requires the absolute unity of subject and object. Maimon therefore criticizes Kant's dualistic divisions between the mental form and extra-mental matter of knowledge, and between the faculties of sensibility and understanding. Experience in Kant's sense - empirical knowledge - is possible only if these dualisms are merely apparent. Our finite minds must be imperfect expressions of an infinite, divine mind that produces the form and matter of knowledge. Through scientific progress, our minds become more adequate expressions of the infinite mind. Kant has not refuted Hume's scepticism, which could be refuted only if science became perfect. Perfect science is an ideal for which we must strive but which we will never reach.

Maimon is deeply indebted to Maimonides, but he reformulates Maimonidean ideas in light of modern mathematical physics and deploys them within a Kantian investigation of the possibility of experience. The result is a unique encounter between medieval and modern philosophy that decisively influenced German idealism and remains philosophically interesting.

1 Life and works

Maimon was born in Sukoviborg, Lithuania, and educated in the Talmud. He studied Kabbalah, was attracted then repelled by early Hasidism (see Hasidism); and, under the influence of Maimonides, migrated to Germany in search of secular wisdom (see Maimonides, M.). Turned away from Berlin, he became a wandering beggar and then taught at Posen, where he composed several Hebrew works. Maimon finally entered Berlin *c.*1780 and was befriended by enlightened Jews associated with Mendelssohn (see Mendelssohn, M.; Enlightenment, Jewish). However, Mendelssohn advised him to leave Berlin because of the tensions arising from Maimon's reluctance to earn a livelihood and from his sensuous lifestyle. Maimon studied German and contemporary philosophy and science. After returning to Berlin, Maimon's critical notes on Kant's *Critik der Reinen Vernunft (Critique of Pure Reason)* were forwarded to Immanuel Kant by Markus Herz, Kant's student, physician and friend in 1789. Kant realized the work's excellence. The notes were published (1790), followed a year later by a Hebrew commentary on Maimonides (1791). These works laid the foundations for a decade of publication, during which Maimon contributed to almost every area of contemporary philosophy. Influenced by Maimonides's naturalistic account of prophecy, Maimon pioneered the scientific study of parapsychology (see Parapsychology). He also argued that Maimonides' ideas could solve contemporary philosophical problems. Maimon polemicized against Reinhold and Schulze, and exercised great influence upon Fichte. His financial problems were alleviated when Count Kalkreuth offered to house him, and he died in 1800 at Kalkreuth's estate in Nieder-Siegersdorf, where he was buried outside the Jewish cemetery. His autobiography (1792/3) provides important testimony about eighteenth-century Jewish life.

2 Criticism of Kant's dualism

Maimon severely criticized Kant's attempt to refute Hume's scepticism. Hume had argued that our claims to find necessary (for example, causal) connections between events are justified neither by logic (because there is no contradiction in denying such connections) nor by experience (because we experience what is, not what must be) (see Hume, D.). Kant responded that experience is impossible unless we regard such connections as necessary, which cannot be derived from logic or experience but are justified as necessary conditions for the possibility of experience. These necessary conditions are the categories of the understanding (see Kant, I.). However, Maimon argues that Kant understands experience differently from Hume. For Kant, experience is empirical knowledge - organized information about the sensible world. But for Hume, experience is an unorganized body of sensory impressions. Kant has not refuted Hume because Hume need not concede that we have experience in Kant's sense, so he need not concede that its necessary conditions are justified.

Furthermore, Maimon argues that Kant has failed to specify necessary and sufficient conditions for applying the categories to sensory impressions. Kant cannot explain how we apply the categories, whereas Hume explains that we claim necessary connections because we become accustomed to associations among events of certain types.

In Maimon's view, Kant's failure arises from the twofold dualism he attributes to the human mind. First, the mind is divided from the things in themselves that produce the matter of sensation. Second, the mind is divided into two faculties, each supplying its own form. Sensibility supplies space and time, while the understanding supplies the categories. Maimon argues that the categories can be justifiably applied only if the mind produces sensations, matter as well as form - thus, only if sensibility and understanding are not distinct. Empirical knowledge is possible if Kant's dualisms are overcome, if Kant's divergent mental faculties are only apparent features of the human mind, which is in reality an imperfect expression of the divine mind, generating both the form and the matter of experience.

To explain how experience is possible, then, Maimon rethinks Kant's central notions. He understands the thing-in-itself not as an extra-mental reality but as the reality known by the infinite mind. The thing-in-itself is the goal of scientific progress and not, as Kant thinks, the unknowable substratum of experience.

To overcome the dualism between sensibility and understanding, Maimon rejects Kant's view that space and time are non-conceptual forms of sensibility. Instead, he regards them as the minimal conceptual conditions for thinking diverse objects. Diverse objects must be the same in one respect and different in another, so two forms are required: the objects might occupy the same space at different times or different spaces at the same time. Whereas Kant takes space and time to be objects of intuition, Maimon regards them as concepts, misleadingly represented as objects of intuition by the imagination.

Maimon overcomes the dualism between sensations and the categories by drawing on the infinitesimal calculus as developed by Leibniz. He regards sensations as composed, not of passive affections, but rather of differentials or infinitesimal degrees of mental activity below the threshold of consciousness. Instead of pertaining to a distinct faculty of sensibility, these differentials are ideas of understanding: they are the elements that the understanding would ideally reach if it carried out an infinite analysis. For its part, the understanding seeks to know objects in their genesis, and its categories are rules for the production of objects. To categorize a sensation is to grasp the law-like relationship between its differentials (dy/dx) through which a sensed object is produced. There is no gulf between sensations and the understanding, so the categories can be applied to sensible objects - and experience is possible.

3 Rational dogmatism and empirical scepticism

To some of Maimon's contemporaries, these monistic revisions of Kant suggested a way to refute Hume. But Maimon thinks Hume cannot be refuted, for although empirical knowledge is possible, it is not actual. This empirical scepticism follows from Maimon's rational dogmatism about knowledge, which in turn arises from his unique combination of Maimonides's medieval Aristotelianism with an understanding of mathematics based on the modern accomplishments of Leibniz and Newton (see Maimonides, M.; Leibniz, G.W.; Newton, I.).

Maimon is dogmatic about the conditions prescribed by reason for the attainment of knowledge: knowledge requires the absolute unity of the subject, the object and the act of knowing. Thus in arithmetic, he claims, we produce mathematical objects (numbers) without any input from outside the mind; and there is no real distinction between our number-generating minds, the numbers generated, and the rules by which we generate them. Maimon combines this modern understanding of mathematics as creation with a medieval understanding of God. Maimonides attributed to the philosophers the (Aristotelian) dictum that God is the intellect as well as the intellectually cognizing subject and the intellectually cognized object. He also said that God is always engaged in actual knowing and is therefore always absolutely one, whereas we attain absolute unity only if we actualize our potential for knowledge. On Maimon's interpretation, God is the mathematical mind that generates the world, and we can know the world in so far as we understand the mathematical rules of its generation. Experience (empirical knowledge) is possible if we are made in God's image or, in Maimon's formulation, if the finite mind is the schema of the infinite mind. When we engage in mathematics, we are divine.

So Maimon rejects Kant's dualisms, not only because Kant's response to Hume is inadequate, but also because dualism is incompatible with knowledge. He believes experience can be actual only if we eliminate dualism from

science and become one with God. However, this is an ideal, for which we must strive but which we can never attain. So Hume is right to be sceptical about our claims to actual empirical knowledge.

Maimon's remarks about mathematics suggest that even mathematics is tainted by dualism and must be transformed before experience is actual. Symbolic proofs explain why premises imply a conclusion, but they may employ unreal concepts, such as 'regular dodecahedron'. In contrast, constructions in intuition, such as geometric figures, can show that a concept is real, but not why. The dualism of symbol and intuition must be eliminated, creating a mathematics that, at present, cannot even be imagined.

The moral of Maimon's scepticism is not despair but a commitment to scientific progress and intellectual honesty. We must strive for perfection without pretending we are already perfect (see Scepticism).

4 The categories and the principle of determinability

As rules of production, Maimon's categories differ from Kant's, which are empty forms derived from the forms of logical judgment. Dissatisfied with Kant's reliance on traditional logic, Maimon reconsiders Aristotle's pioneering account of the categories and logic. He undertakes to derive the categories and the forms of judgment from a first principle, rendering logic a systematic science at last.

He proposes the principle of determinability: in a judgment determining a real object, the subject can be thought without the predicate but not the predicate without the subject. The infinite mind may be conceived as a single chain of judgments, beginning with the principle of determinability, determining every subject by a unique predicate, and culminating in the thing-in-itself as the fully determinate object of experience. This monistic system is akin to that of Spinoza. But we cannot complete it - only approximate it as science progresses.

5 Practical philosophy

Maimon rejects Kant's doctrine of the primacy of the practical. This is the doctrine that reason seeks an absolute ground, but entangles itself in contradictions and illusions when it seeks that absolute ground through the scientific pursuit of knowledge, whereas reason finds an absolute ground in the practical pursuit of moral action. In Maimon's view, reason can find an absolute ground through the scientific pursuit of knowledge, if dualism is eliminated. Contradictions and illusions arise only when reason conflicts with imagination. Maimon's ethics are closer to Maimonides and Aristotle than to Kant, and he undertakes to derive morality from theoretical reason (see Maimonides, M.; Aristotle).

Maimon is committed only to religious doctrines reconcilable with reason. He finds Jewish monotheism more rational than Christianity and praises rabbinic morality, but criticizes the artificial development of Jewish law since the destruction of the Temple and does not oppose conversion to Christianity, if it is pursued for the sake of one's intellectual development. Maimon himself attempted conversion but, when he declared himself committed to rationalizing Christianity and uninterested in it for its own sake, he was rejected as too much of a philosopher to be become a Christian.

Maimonides, Abraham ben Moses (1186-1237)

Jewish theologian, mystical pietist, physician, and the only son of Moses Maimonides, with whom he studied rabbinics, philosophy and medicine. Upon his father's death, Abraham became the spiritual and temporal head of Egyptian Jewry and a leading rabbinical authority. Using this position, he propagated a form of Jewish pietism, introducing ideas and ritual practices inspired by Islamic mysticism. Moving beyond defence of his father's legal and philosophical writings, Abraham's most important work, Kifayat al-'Abidin (Complete Guide for Devotees) - a monumental compendium of jurisprudence and religious philosophy - develops his own pietist interests. It attracted something of a following in its time but also met with concerted Jewish opposition to its Sufi-inspired ideals.

Born in Fustat, Egypt, Abraham showed exceptional gifts that were noted from an early age. In 1204, a time of temporal and spiritual upheavals, he was chosen, a youth of eighteen, to lead Egyptian Jewry, the first of his family to occupy the office of *rayyis al-yahud*, which would become hereditary and remain in the family for two centuries, in large part because of the prestige of their distinguished ancestor Moses Maimonides. An able administrator and a constructive activist as well as a theorist, Abraham enjoyed close relations with the Muslim authorities as court physician to the Ayyubid ruler al-Malik al-Kamil. Much of his writing, perforce, was devoted to defending his father's works against their rabbinical and philosophical detractors. His *Milhamot ha-Shem (Wars of the Lord)*, written after 1235, responded in particular to the criticisms of the rabbis of Provence.

Abraham wholeheartedly espoused his father's philosophical system and was seen as a continuator of the Arabic Aristotelian tradition. But his mature views diverged widely and creatively from such ideas. Moses Maimonides had considered the ultimate human aim to be knowledge of God, but the son stressed ethical perfection. His ascetic mysticism earned him the epithet by which he is consistently cited in later literature, Abraham *he-hasid* ('the Pious'). Identifying with a pietistic circle who were dissatisfied with the rationalism of some contemporary peripatetics, Abraham brought Sufi ideals into traditional Judaism, inspired by Abraham Abu'l-Rabi'a (d. 1223), also known as *he-hasid*, whom he calls 'our master in the Way'. He became the leader of this circle, whose adepts included his father-in-law, Hanan'el ben Samuel, and his own son 'Obadyah (1228-65), author of the mystical *al-Maqala al-Hawdiyya (The Treatise of the Pool)*.

Pressing his prerogative as *nagid* (communal leader), he tried to enforce pietistic practices on the larger community, much as his father had sought to introduce various ritual reforms. Abraham's far-reaching measures included such Islamic-influenced practices as ablutions of the feet before prayer, sitting in a dignified posture during prayer, standing in rows, raising the hands in supplication, and punctuating prayer with profuse prostrations.

Abraham defended his pietism in the *Kifayat al-'Abidin (Complete Guide for Devotees)* (written *circa* 1230). This monumental legal and ethical treatise is not extant *in toto*, but substantial manuscripts survive in Genizah collections. Regrettably, the final section, dealing with *wusul* (the mystical goal), seems to be lost.

Written in Arabic in a warm and attractive style, the work is well constructed. The early parts rehearse the legal rulings of Abraham's father, albeit in a distinctively spiritualized vein. But the fourth and final section, on the 'special way', highlights the virtues of *tariq* (the path): sincerity, mercy, generosity, gentleness, humility, faith, contentedness, abstinence, mortification and solitude. These are *maqamat* (stages or stations), well known in the classical Sufi manuals. The goal, *wusul* ('arrival'), is in both cases encounter with God and the certitude of his light.

Abraham openly admires the Muslim Sufis, whose practices, he claims, derive originally from the prophets of Israel (see Mystical philosophy in Islam). He even finds a Jewish origin for Sufi self-mortifications - combating sleep, solitary retreats in dark places, weeping, nightly vigils and daily fasts. Notable is the obligation of the novice to take as his guide an experienced teacher who has traversed all the stages of the path and will initiate the novice in the intricacies of mystical discipline before bestowing on him his mantle, as Elijah did on Elisha.

Departing from the juridical mode of his father's legal code, the *Mishneh Torah*, Abraham stresses the spiritual significance of the traditional Jewish precepts (*mitzvot*, divine commandments) and the 'mysteries' they conceal,

in much the same manner of al-Ghazali's classic Islamic summa, the *Ihya' 'ulum al-din (Revival of the Religious Sciences)* (see al-Ghazali). The idea that Abraham Maimonides had rediscovered lost mysteries of Jewish provenance in traditions preserved by the Sufis but long forgotten by the Jews in the tribulations of their exile allowed his circle to justify their adoption of Muslim customs and symbolisms. Calling themselves 'the disciples of the prophets', the Jewish pietists confidently awaited the imminent renewal of prophecy in Israel. The ancient Jewish traditions recovered from the Sufis were integral to the 'prophetic discipline'. Restoration of that discipline would hasten the return of prophecy itself, which Moses Maimonides had predicted in principle, but for a seemingly remote and certainly unspecifiable date.

Abraham had intended to compose a biblical commentary, but only the sections on Genesis and Exodus seem to have been completed, some time after 1231. Here, as in the *Kifayat*, he gives free reign to his mystical predilections, often, for polemical reasons, projecting into the patriarchal past his own innovations, depicting ancient biblical figures as pietists in much the way that Sufi literature clothes Muhammad and his companions in the garb of the early Sufis. He often alludes to an esoteric interpretation of the 'subtle mysteries' of the Pentateuch. These are not mentioned in his father's system. They typically point to pietist doctrines.

Although intended to enhance the spiritual ambience of Jewish worship with new forms of decorum like those to be observed among the Muslim neighbours of the Egyptian Jews, the novel practices Abraham Maimonides championed did not go unchallenged. Despite his office and familial prestige, which furthered pietist aims immensely, Abraham confronted fierce opponents, who went as far as to denounce him to the Muslim authorities, accusing the Jewish pietists of introducing 'false ideas', 'unlawful changes' and 'gentile customs' into the synagogue.

This opposition, and the spiritual elitism that had characterized the movement from its inception, may explain why it never gained universal approval. With the general decline of Oriental Jewry, Abraham Maimonides' construction of a Sufi-influenced Jewish pietism, gradually sank into oblivion.

Maimonides, Moses (1138-1204)

*Called the Rambam in the Hebrew sources, an acronym on his name, and known in Islamic texts as Musa ibn Maimun, Rabbi Moses ben Maimon is best known in the West as Moses Maimonides and generally recognized as the greatest of the medieval Jewish philosophers. Maimonides lived his mature life in Egypt and earned his living as a physician. He was the author of ten medical works but gained fame in his own lifetime from his work on Jewish law (*halakhah*), chiefly the Kitab al-Fara'id (Sefer ha-Mitzvot, that is, the Book of the Commandments), cataloguing the traditional 613 commandments of the Pentateuch; Kitab al-Siraj (Sefer ha-Maor, Perush ha-Mishnah, Commentary on the Mishnah); and, above all, the Mishneh Torah (The Law in Review), a comprehensive and still authoritative code of rabbinic law. The clarity and definitiveness of the Mishneh Torah led to its criticism and (after Maimonides' death) even condemnation by some rabbis, who prized the ongoing dialectic of Talmudic disputation and felt suspicious of Maimonides' rationalism.*

Maimonides' philosophic masterpiece, the Dalalat al-Ha'irin or Guide to the Perplexed, was written in Arabic, with a view to helping the more intellectually inquisitive readers of the Torah, who were troubled by the apparent disparity between biblical and scientific/philosophical ideas. The work frames a powerful but not supercilious rationalism that locates and accommodates many biblical postulates and profits from the instruction of the rabbinic (Talmudic) sources and from critical appropriation of the achievements of Muslim philosophers and theologians and their Greek predecessors. It defends the doctrine of the world's creation against the eternalism of Neoplatonic Aristotelians but rejects the notion that creation (or eternity) is subject to proof. Rather, Maimonides argues, creation is preferable to its alternative, and more plausible, because it preserves the idea of divine volition as an explanation for the emergence of complexity from divine simplicity, and because it marks the difference God's act made to the existence and nature of the world.

God is pure perfection and absolute simplicity. The Torah's anthropomorphisms themselves lead us to that realization, if we follow the dialectic by which prophetic language directs us to ever higher conceptions of divine transcendence. Biblical poetry and the concrete demands of the Law are accommodations to our creaturely limitations. Such accommodations are made possible by the material side of the prophet's nature, as manifested in language and imagination, which are, no less than intellect, expressions of God. For matter in general is an expression of God, apprehensible to us through what seems wilful or arbitrary in nature. It is not a positive principle or hypostasis, but it is a necessary concomitant of the act of creation itself. For without it nothing other than God would exist. Our task as humans is to discipline our material natures - not to battle or seek to destroy them but to put them to work in behalf of our self-perfection, through which our inner, intellectual affinity to God will be realized.

Maimonides' synthetic approach, accommodating to one another the insights of reason and the teachings of Scripture and tradition, was highly valued by Aquinas, who frequently cites him, and by other European philosophers such as Jean Bodin. Leibniz warmly appreciated Maimonides' thought, as his reading notes reveal. Among subsequent Jewish thinkers, Maimonides' work became the paradigm of Jewish rationalism for his admirers and detractors alike. His philosophy was at the core of the philosophic tradition that Spinoza addressed. Even today practitioners of Jewish philosophy stake out their positions in reference to Maimonides and formulate their own views as appropriations, variants or interpretations of the elements of his thought.

1 Life and works

Called the Rambam in the Hebrew sources, an acronym on his name, and known in Islamic texts as Musa ibn Maimun, Rabbi Moses ben Maimon is best known in the West as Moses Maimonides and generally recognized as the greatest of the medieval Jewish philosophers. A physician and jurist as well as a philosopher, Maimonides was born in Cordoba, but his family fled the forced conversions of the Almohad invasion in 1148. From about 1160 they lived quietly in Fez, the heart of the Almohad movement, but came to public attention with the youthful Maimonides' publication of a defence of a rabbinic ruling his father had made promulgating full acceptance by the Jewish community of those who had undergone a nominal conversion. Journeying to Palestine in 1165, the family were nearly lost in a storm at sea but made their way to Acre. Maimonides prayed at the ruined Temple site and fulfilled a shipboard vow of pilgrimage to Hebron, burial site of the biblical patriarchs. Abraham bore a special

significance for Maimonides. In keeping with the biblical and midrashic tradition, he viewed the patriarch as a natural theologian whose religion was formed not in the tradition of his fathers but by reason confronting nature and experience.

Finding permanent residence impossible in the undeveloped land, then under the Crusader kingdom of Jerusalem, the family settled in Cairo, where Maimonides was prostrated with grief by the death of his younger brother David, a jewel merchant, in a shipwreck on the Indian Ocean. Recovering and taking over the support of the family, Maimonides turned to medicine. Like the ancient Talmudic sages, he disdained making his livelihood from his Judaic learning and judicial authority. He developed an active medical practice and became court physician to the *wazir* of Saladin, who overthrew the Fatimid dynasty in 1171. Late in life Maimonides wrote ten medical treatises, but it was his work in rabbinic law that gave him fame and made him a leader of the Egyptian Jewish community as early as 1167.

Three works secure his place among the greatest rabbinic jurists: his *Kitab al-Fara'id*, known in Hebrew as the *Sefer ha-Mitzvot*, cataloguing and classifying the traditional 613 biblical laws, lays the foundations; his Arabic *Kitab al-Siraj* or *Book of the Lamp*, known in Hebrew as the *Sefer ha-Maor, Perush ha-Mishnah* (1168), expounds the rational purposes of the ancient rabbinic code; and his *Mishneh Torah* (*c.*1185), written in rabbinic Hebrew and popularly known as the *Yad Hazakah (The Strong Hand)*, or simply the *Yad*, an allusion to its fourteen volumes, since the numerical value of the letters of the Hebrew word *yad*, or hand, is fourteen. This work organizes the vast complexity of Talmudic and post-Talmudic Jewish law in a still authoritative codification, allowing clear access to definitive legal rulings on matters of *halakhah* (see Halakhah).

Despite the prestige of these works - in part because of it - Maimonides' jurisprudence was not universally hailed. The *Mishneh Torah* in particular was criticized: its title, which might be rendered 'The Law in Review', and which echoes a title traditionally assigned to the biblical book of Deuteronomy, seemed almost to promise a second revelation. The economy of the work, which placed a premium on stating clear-cut practical decisions, demanded the omission of rabbinic citations and dispensed with the voluminous dialectic which for many was the heartsblood of the Law as an intellectual discipline, even a way of life.

Maimonides was in fact sometimes impatient with the digressive and midrashic (homiletical) methods of rabbinic discourse. His insistence on juridical clarity, determinateness and Socratic conceptual organization (as sharply contrasted with the associative exposition of the Talmud) were clearly much on his mind when he turned from writing commentaries on parts of the Talmud to his more distinctive commentary on the Mishnah. The notion that study of the law could somehow supplant the robust life that the law meant to regulate seemed especially unwholesome to him - as it had to his Andalusian predecessor Judah Halevi.

A brilliant and faithful jurist, Maimonides drew the axioms of his theology from scriptural rather than rabbinic sources; he worked eclectically and creatively with the rabbinic responses to biblical ideas to forge a coherent and appropriable framework of thought - just as his rabbinic predecessors had done. But traditionalists, legal positivists and fideists could not fail to note that where Maimonides could not find room to cite his legal authorities (and some of them are still being found, giving the lie to long-standing claims that he based some of his legal doctrines sheerly on his own opinions) he did make room, in the first volume of his code, to frame a thematic ethics and to elaborate a natural theology and cosmology - and, in the last volume, to develop a biblically grounded theory of sovereignty and public law. Similarly, he does not regard it as digressive in discussing the laws of penitence to include a defence of human freedom of will. Reacting against what they viewed as an excessive rationalism, a number of rabbis condemned the *Mishneh Torah*, although others defended it vigorously. Denounced to Church authorities by Jewish adversaries, the first and most thematic volume of Maimonides' code, the *Sefer ha-Mada (Book of Knowledge)*, was burnt at Montpellier in 1232, along with the seemingly heretical *Guide to the Perplexed*. Despite the reservations of some Jewish traditionalists to this day about the rationalism of his philosophical and jurisprudential work, Maimonides remains a towering figure in *halakhah*. His work is the cornerstone of all subsequent Jewish philosophy, and it has had a significant impact on philosophy at large. His synthetic approach, accommodating to one another the insights of reason and the teachings of Scripture and tradition, was highly valued by Aquinas, who frequently cites him, and by other European philosophers such as Jean Bodin. Leibniz warmly appreciated Maimonides' thought, as his reading notes reveal. Maimonides' work became the paradigm of Jewish rationalism for his admirers and detractors alike. It was a major philosophic

backstop to the thinking of Spinoza, providing a clear paradigm of the committed Jewish philosophy that Spinoza would address, whether by way of refutation, accommodation or revision. Even today practitioners of Jewish philosophy stake out their positions in reference to Maimonides and formulate their own views as appropriations, variants or interpretations of the elements of his thought.

2 *Guide to the Perplexed*: its literary form and intent

Maimonides' philosophic masterpiece, *Dalalat al-Ha'irin (Guide to the Perplexed)* (*c*.1190), was written in Arabic but widely circulated in Hebrew translations as the *Moreh Nevukhim*. Aiming to mediate between the scriptural and philosophic idioms, it opens by deriving a sophisticated negative theology from a subtle deconstruction of the anthropomorphisms that had long troubled thoughtful readers of the Torah. This discussion, filling the first seventy chapters of the *Guide*, is widely but erroneously read as a refutation of anthropomorphism. I say erroneously, because Maimonides assumes that the falsity of anthropomorphism is well established by argument and well known to his reader. But Maimonides does not do much to prevent such misprision. He does not state the objective of his discussions in this extended section of the first part of the *Guide* but leaves casual readers to fend for themselves. One natural outcome is the commonplace assumption that what Maimonides takes for granted is what he is seeking to prove. That, in Maimonides' view, is better than allowing his philosophic work to do more harm than good.

The difficulty that Maimonides confronts is this: the *Guide* is written to aid a reader who is confused by the seeming disparity between biblical and scientific/philosophical ideas. To mention only the most obvious issues: Scripture tells us that the world is created, but Aristotelian philosophers present numerous proofs to show that the world has always existed with the same, invariant nature that we observe today. Scripture speaks of God as the ruler of nature and the lawgiver of humanity in general and of Israel in particular. But the philosophical tradition argues that the divine transcends all knowledge of particulars, let alone concern for them. Indeed, it is readily enough argued that chance seems to rule, in this life at least, and that sufferings outweigh happiness. So where are the divine justice and judgment that loom so large in the vision of the Torah and the prophets? How is prophecy even possible, if God is so far above us as philosophy seems to teach? And how can we relate the philosophical teaching of divine transcendence to the vivid concreteness of prophetic imagination?

Maimonides unifies these problems about transcendence and immanence, providence and revelation, creation and eternity, finitude and privation under the rubrics of two rabbinic problematics: the account of creation and the account of the chariot. The first rubric alludes to the opening of Genesis, the second to that of Ezekiel, in whose epiphany, despite all his reverent periphrasis, God seems to take human form. Voicing a sense of the paradox or mystery surrounding these two passages, the rabbis of the Talmud (Haggigah 11b, 13a) forbade public instruction in the issues they involve. Only in private teaching were these to be discussed, and then only the subject headings were to be broached.

Interpreting this ruling, Maimonides understands 'the account of Genesis' as the rabbis' name for cosmology, the principles of nature or physics, understood in relation to God; 'the account of the Chariot' is, by metonymy, the entire realm of theology, that is, metaphysics understood in relation to God. The core issue in both cases: how can the Infinite be manifest in finite terms?

The cosmological side of this question is evident in the Neoplatonists' problematic of the Many and the One - why is there anything other than God? It crops up polemically in the sensitive and vexed area of creation, where philosophers of Aristotelian stamp find it incongruous to ascribe an origin to the world, in part because their naturalism balks at subjecting the cosmos to external interference but in part because they wish to avoid compromising divine transcendence in temporality.

Viewed in this light, creation itself appears to be an instance of theophany. The problem of evil and that of prophetic revelation reflect the same issue: why does divine creation content itself with a world as flawed as this one? Why would revelation single out one people or individual to hear God's word, leaving others dependent or unenlightened altogether; and why should God's expression, as epiphany or as law, take the precise form ascribed to it by individual prophets, with all their human weaknesses and differences of outlook and circumstance?

The ordinary mind, Maimonides finds, is generally content to accept what is familiar, not noticing the difficulties a tradition may contain. But such faith, if faith it may be called, is of limited value and entirely dependent on the

veracity and coherence of those who establish a tradition. In the strictest sense, such unreflective acceptance is not faith at all. For belief is commitment to what one understands; it cannot be confined to mere conformity.

To the more questioning, especially those who have read scientific and philosophical literature, theological problems are apparent. Responsible intellectual leaders must work creatively to discover for themselves and show others how these problems can be addressed. Progress here, as in other areas of intellectual inquiry, is possible. Indeed, our progress towards God can be asymptotic, Maimonides argues, invoking the geometrical image of two lines that grow ever closer together, even though they will never meet. But progress, to be cumulative, requires writing and teaching, and that presents a difficulty; it is not responsible to introduce others to problems whose solutions they might not grasp. Maimonides takes this issue very seriously, holding a teacher responsible even for the misinterpretations of followers and disciples.

Taking a hint from the language of the ancient Talmudic restriction, Maimonides adopts an ‘esoteric’ mode of writing in the *Guide*. Not that he writes obscurely or treats his subject as occult or hermetic. He simply does not state the problems to be addressed. A reader who has grappled with the same questions will readily enough discover the relevance of the discussions in the *Guide*. But that relevance is not spelled out - let alone promoted in the mercantile manner of twentieth-century pedagogy. The order of exposition, moreover, as with the texts that Maimonides studied most closely - the Hebrew Bible, the Talmud, the Aristotelian corpus - demands that one read well into the text before being able to make much of it, since every part is relevant to the rest, and no passage is wholly self-explanatory or transparent.

Maimonides’ work, like Aristotle’s, and the Jewish canonical sources, is clearly not part of the Cartesian modernist project, with its Euclidean pyramidal structure, designed to move upwards from foundational axioms, postulates and definitions to theorems, scholia and lemmas. Rather, the work is bound together like a Gordian knot - not impenetrable, but resistant to simple unravelling by the teeth and fingers of the unprepared.

Uncritical thinking is probably just as common today as it was in Maimonides’ time, but exposure to doubt and (somewhat conventional) lines of objection to biblical categories and assumptions is far more widespread. Today’s unexamined faith is often a form of scepticism. So the *Guide to the Perplexed*, although written to address specific issues at a very particular historical juncture, has the character of a classic - not only because it is synthetic, original and insightful, but also because readers today find its approach and many of its arguments as relevant as when first set down.

Following the rabbinic injunction that the problems of creation and theophany are to be taught not publicly but in a direct and idividual communication, Maimonides adapts to his purposes the Arabic literary genre of the epistolary essay (*risala*). The *Guide* is written in the form of a letter addressed to a particular disciple, whose needs and questions can be addressed in an informal, dialectical style, rather than the formal, systematic style of a treatise like the *Mishneh Torah*. Having sketched the background, skills and uncertainties of this first intended reader, Maimonides has created a persona, not in the authorial voice but in the figure of the reader, clearly alerting others to the scope and relevance to their own concerns of the arguments they will encounter.

In keeping with his expository strategy, Maimonides never calls the *Guide* a book. He moves with seemingly casual, conversational rhythms from exegetical remarks to philosophical observations, arguments, typologies and critiques, relying on sensitive readers to follow his hints, supply the unstated problematic, and piece together the larger argument. He well understands that the broader impact of the opening chapters will be fully felt only by readers who take the time and trouble to read them once again after having progressed through the work as a whole.

It might seem that Maimonides has simply employed a legal fiction, and a thin one at that, to skirt the rabbinic restriction on the sort of teaching he wants to pursue. But his strategy is far subtler than that. He has successfully kept the *Guide*’s problematic within the circle of its intended audience. Casual readers typically emerge from an encounter with the *Guide* without any knowledge of its subject matter; most casual readers do not finish it, let alone begin again, so as to be able to piece together the scattered elements of its larger argument.

3 *Guide to the Perplexed*: creation and eternity

If we begin not where Maimonides did, with the deconstruction of biblical anthropomorphism, but where Genesis

does, with the beginning, we find Maimonides in a spirited defence of the idea of creation against the eternalism of al-Farabi, Ibn Sina, Aristotle, and the whole Neoplatonic Aristotelian tradition (see Eternity of the world, medieval views of). The problem is not, Maimonides argues, that philosophical proof contradicts scriptural dogma. On the contrary, if we had proof that creation was impossible, as Aristotelian philosophers long argued, we would simply allegorize the biblical account of creation, just as we allegorize biblical anthropomorphism. But Aristotle knew that he had no such proof. That is why he speaks so emphatically when he tries to assure us of the world's eternity. After all, it was he who taught us the difference between proof and mere persuasion.

What the philosophers of the Aristotelian tradition have done is simply read into the metaphysics of being the familiar character of nature: no event without a prior event, no process without potentiality, no potentiality without matter as its substrate. Of course assumptions like these will generate an eternal cosmos. But they amount to nothing more than an aprioristic attempt to generalize the conditions of the settled order of nature and impose the assumptions we derive from study of that order on the wholly unknown conditions of the world's disputed origin - as if a brilliant young man who knew nothing of sex or procreation were to infer the impossibility of embryogenesis and foetal development from his knowledge of the biology of mature adults: how could a human live in an enclosed sac, without breathing, moving about, ingesting solid food, or excreting bodily wastes?

Rejecting efforts to demonstrate the world's eternity, Maimonides even-handedly rejects creationist attempts of the same sort. If it is really true, he argues, that the world must reflect God's timelessness, as eternalists suppose, then change itself becomes impossible, and the argument has proved too much. If the claim is that God, to be a creator, must be a constant creator, then creation becomes not impossible but necessary. Those who try to demonstrate creation, not surprisingly, produce a similar result: the world is new at every instant. The radical occasionalism of Arabic dialectical theology that results from such thinking, Maimonides argues, renders nature unintelligible and divine governance irrational (see Islamic theology §§1-2; Occasionalism). Creation, in that case, to be the outcome of a clear proof, must cease to be God's choice and become a sheer necessity and unending chore.

But, although efforts to demonstrate the world's creation or its eternity fail, there are grounds for choosing between the rival cosmological visions. Creation is more plausible conceptually and preferable theologically: more plausible, because a free creative act allows differentiation of the world's multiplicity from divine simplicity, as the seemingly mechanical necessitation of emanation, strictly construed, cannot do; preferable, because Avicennan claims that God is author of the world and determiner of its contingency are undercut by the assertion that at no time was nature other than it is now (see Ibn Sina). Without the notion of creation at a particular time, one cannot say that atheism ensues, as al-Ghazali had supposed. The view of the Neoplatonic Aristotelians is neither incoherent nor insincere. But it does unduly attenuate the world's dependence on God's act, and it does leave unexplained the emergence of complexity from simplicity - problems which the human idea of a will that is not simply reducible to intellect or understanding far more readily addresses.

4 *Guide to the Perplexed*: God's governance of nature

In discussing God's governance of nature, Maimonides adopts and adapts the emanative ideas of the Neoplatonic philosophers (see Neoplatonism). But he modifies their notion that emanation is a necessary progression, poetically compared to the radiation of light from the sun (which, after all, cannot help but shine) but more perspicuously described in terms of the necessitation of theorems by their axioms. In place of such deductivist, intellectualist models, Maimonides uses a more voluntaristic model, allowing for creativity and novelty in nature's unfolding, while rejecting the more radical voluntarism of the occasionalists, who make God the immediate author of all events, without the intervention of natural causes or human volitions (see Voluntarism). If persons and things do not act and react, Maimonides argues, was it not otiose of God to create foodstuffs that play no role in our sustenance, or to ordain commandments that we have no power to obey or disobey?

Taking the Neoplatonists to task for not exploiting adequately the resources of their own ontology for addressing the problem of evil, Maimonides couches his response to the Epicurean dilemma in a gloss on the Book of Job. The Satan (or 'adversary') responsible for Job's sufferings, he notes, is not called one of the 'sons of God' but is said only to have come along with them, 'in their midst'. One might suppose, with the Talmudic sage Resh Lakish, that Job's adversary was sin - equating sin and death with the adversary (see Sin). Maimonides likes the allegory but rejects its application here. For it is a premise of the Book of Job (which Maimonides, like Resh Lakish, quite clearly takes to be a fiction, although he regards it as one with considerable verisimilitude) that Job was without

sin (see Evil, problem of).

The Satan, then, would be Job's vulnerability, that is, his materiality, the physical nature that makes us all subject to sufferings and loss. For, as Galen explained, one should not expect bodies of the sort of matter that makes our own to last forever. Here we see the weight of Scripture's saying that the Satan came 'in the midst of' the sons of God: matter, that is, otherness, alienation from the unity of the Divine, is not a positive principle, a hypostasis, angel or Form, but a concomitant to the emergence of finite being, a requisite of creation and createdness. The existence we enjoy has vulnerability as its price; divine generosity could not be expressed and vouchsafed to lesser beings at all unless those beings were indeed made other, given a reality that is at once their own and (by the same token) inevitably deficient. Matter is that independence and deficiency. It is at once the good woman of Proverbs 31, constantly active on our behalf, and the married harlot of Proverbs 7, never contented but constantly changing forms/partners.

Our human task is to overcome the limitations of matter, but we can do so through its strengths. Thus mortification of the flesh is not a worthy but an unwholesome ideal, based on the illusion that if a little medicine is good for us a lot will be that much better. Medical arts, politics, and otherworldly endeavours are precious but instrumental efforts, since they sustain the human individual and community, allowing us the necessary time and opportunity to seek and reach the human goal.

What is that goal? Maimonides categorically agrees with Plato (*Theaetetus* 176b) and Leviticus (19:2): it is to become as like to God as humanly possible, to emulate and pursue God's holiness, to realize and fulfil what is divine and holy in ourselves. Job's reward is not in the restoration of his family and possessions but in the epiphany he is granted, a communion with God that is not the recompense of his sufferings but an emblem of the sort of human attainment that makes all sufferings if not bearable then at least outweighed.

It is not true, as Muhammad ibn Zakariyya' al-Razi and even Saadiah Gaon supposed, that sufferings overbalance good fortune in this life. But the deeper flaw in the emotively appealing notion that life is a vale of tears is that it assays human life in terms of pain and suffering, whereas the ultimate coin is not hedonic at all but intellectual. Reason is the surest guide to the good life and test of sound and unsound norms and precepts; but it is also our closest bond with God, our purchase on immortality, and the focus of divine providence within us. For providence, in the human case, is not confined to the level of the species and its generalized nature. Indeed, it was Aristotle, once again, who taught us that only individuals are real, not species as such.

Contrary to the Aristotelian teaching (expounded by Peripatetics such as Alexander of Aphrodisias in the face of the Stoic doctrine of providence - see Alexander of Aphrodisias; Stoicism §20), providence does extend to the individual, through our capacity to perfect the mind, realize our inner affinity to God, and grasp the immortality that lies so close at hand. This is symbolized in the biblical account of Adam, whose ready access to the fruit that would give him eternal life represents not a long vanished moment of apotheosis in the mythic past (and still less a damning fall) but the universal human condition, of an immortal intelligence strapped to a body that is at once its trap and its springboard to the divine.

5 *Guide to the Perplexed*: anthropomorphism and the human connection with God

Quietly celebrating the human affinity with God, Maimonides (as noted by the medieval commentator Narboni) begins his survey of biblical anthropomorphisms with 'image and likeness' (see Narboni's *Be'ur le-Sefer Moreh Nevukhim (Commentary on the Guide)*: I 1). Maimonides explains that some Hebrew words (as, for example, when we read that Joseph was fair of form) denote only physical appearance; but 'likeness' can refer to spiritual affinities. Thus in Psalms (102:6), the psalmist likens himself to a pelican in the desert: not that he looks like a pelican, but that he is as desolate as a pelican would be in such a place. As his survey proceeds, Maimonides unfolds a hierarchy of meanings, with the most physical at the bottom, social and other senses rising higher, and the spiritual/intellectual surmounting the rest: wherever the Torah applies to God a term that bears physical (or other privative) connotations, that term can always be taken in a higher, spiritual/intellectual sense, and that is the sense we must pursue.

Maimonides does not here refute anthropomorphism but assumes it to have been refuted by well-known arguments based on the incompatibility of divinity with privation. Correspondingly, he pursues the idea of perfection, the opposite of privation, as the notion that orients this hierarchy, as it orients the ladder of love in Plato's *Symposium*

- or Jacob’s ladder in the Book of Genesis. What Maimonides finds here is an ontic hierarchy that fuses higher degrees of reality with higher degrees of intellectuality. He shows that none of the Torah’s anthropomorphisms need be taken literally (‘jealousy’ refers to exclusivity, ‘coming and going’ to manifestation in a human awareness), but in the process he vindicates the legitimacy of conceptualizing the Divine in terms of the human mind (and will).

We begin to see how prophecy is possible, as a human response to the exigency of relating to others the sheer power of Perfection. The Torah, using human language, speaks of action in terms of motion, of existence in terms of matter. Only the Tetragrammaton signifies God directly, signalling nothing more (but nothing less) than the absoluteness of God’s being - ‘I am that I am’. All other epithets only point towards Perfection, assigning to God some notion humanly regarded as a perfection, while other passages systematically exclude the privations concomitant with the perfections known to us. Thus the deconstruction of biblical anthropomorphism is the work of Scripture itself; the Torah teaches of divine transcendence through the medium of ordinary human language. It uses terms intelligible to us through their generality to convey the idea of divine uniqueness. This was what the rabbis meant in saying, ‘Great is the boldness of the prophets’ to speak of the Creator in the language of his creations.

Prophets are historically situated human beings, but they are not and cannot be mere ignoramuses whose minds are magically filled with divine words; nor can they be immoralists, simply plucked up to be inspired. They are and must be wise individuals, filled with the kind of philosophic insight that can grow only within an upright character. But they are gifted also through the material side of their nature, with the language and imagination to body forth these ideas in concrete visions, laws, rituals, poetic and rhetorical symbols, to speak of them persuasively and act on them with conviction.

Prophets themselves learn nothing new from revelation, although it may bring to the surface ideas that were only latent in their minds. The ignorant remain ignorant; but the gift of imagination in the wise, if they are disciplined by the moral virtues, especially courage and contentment, gives wing to ideas, rendering them accessible to the masses and setting them into practice. The message of all true prophets is thus coherent and universal, an expression of the truth itself.

In principle, any philosopher of character and imagination might be a prophet; but in practice the legislative, ethical and mythopoetic imagination that serves philosophy finds fullest articulation in Judaism. Its highest phase, where imagination yields to pure intellectual communion, was unique to Moses, elaborated in Judaism and its daughter religions. This judgment, that the burden of prophetic teaching finds its epitome in the Torah, is no mere subjective preference: it is grounded in intensive study of the means by which the biblical commandments, read thematically, serve to inform human character and understanding. The most general summary of the outcome of that study is in the Maimonidean thesis that the Mosaic law is no mere personal code, private vision or closely held teaching like Abraham’s; nor is it a mere derivative faith. Rather, it is a systematic way of life based on sustained, intellectual contact with the Divine. When courage and contentment - read here ‘self-confidence and independence’ - return, with the restoration of Israel to her land, prophecy will resume among this people, to the great benefit of the nations of the world, who will observe the peace and prosperity of Israel living under God’s law and will flock to follow not her religion but her example. It is this that is to be understood by the lion’s lying down with the lamb: the nations will learn the ways of peace, and Israel will be the little child that leads them (see Prophecy).

God governs through nature. The forms of things are the objective manifestations of his wisdom, intelligible through their fit with the subjective rationality of our own divinely imparted intelligence. Where a human discoverer must take apart the waterclock to understand its workings, the inventor knows it first: his knowledge does not follow but anticipates the design. The same is true with God, whose knowledge is prior to the realities we know, since it is their cause.

But the matter of things, readily enough associated with chance and the irrational, is another aspect of God’s manifestation in nature, the aspect that we would link, through its seeming arbitrariness, with the human faculty of willing. In God’s ultimate and absolute unity, will and wisdom are united; their multiplicity is subjective. So in biblical parlance all the operations of nature but also the workings of sheer chance are ascribed to God. But we humans must always think in human categories, so it is not possible for us, while we live, to grasp the absoluteness

of God's unity and hold in one mental breath what we can conceptualize only as the wisdom and the will of God.

Human finitude, accordingly, denied Moses the vision he requested, of God's face; but a perfect mind allowed him to see God's 'back' - what follows from God, the effects of God in nature, where divine absoluteness becomes specific and can be apprehended as if in attributes like those of a person. God, of course, in his infinitude, transcends personality, as even little children should be taught. Attributes belong only to composite beings. But Moses' request, after all, was a practical one: he wanted to know God so that he would know how to govern; and for practical purposes, we have knowledge of what God is like by examining the attributes that should be perfected in ourselves, the very attributes named in Moses' epiphany: mercy, compassion, justice - and, of course, the human power that all of these presuppose, that of reason, our direct link with the Divine.

List of works

Maimonides, Moses (1168) *Kitab al-Siraj (Commentary on the Mishnah)*, complete translation available in Hebrew only, *Sefer ha-Maor, hu Perush ha-Mishnah*, ed. M.D. Rabinowitz, Tel Aviv: Rishonim, 1948; English translation of the part of the work entitled *Shemonah Perakim (Eight Chapters)*, trans. J. Gorfinkle, *The Eight Chapters of Maimonides on Ethics*, New York, 1912; repr. New York: AMS, 1966.(Expounds the rational purposes of the ancient rabbinic code. *Shemonah Perakim* is a thematic introduction to the mishnaic collection of ethical aphorisms known as *Pirkei Avot (The Sayings of the Fathers)*. It develops a capsule virtue ethics and sketches a theory of action aiming to rebut determinism.)

Maimonides, Moses (*c*.1185) *Mishneh Torah (The Law in Review)*, Books I and II trans. M. Hyamson, *The Book of Knowledge and the Book of Adoration*, Jerusalem: Feldheim, 1974; Books III-XIV trans. as *The Code of Maimonides*, Yale Judaica Series, New Haven, CT: Yale University Press, 1949-72.(Maimonides's authoritative fourteen-volume code of rabbinic law, written in mishnaic Hebrew with a view to providing lucid and comprehensive guidance to the requirements of *halakhah*. The work opens with detailed discussions (in the first volume) of the intellectual and moral foundations of rabbinic law. It closes with an exposition of public law and a description of the Messianic age of Israel's political restoration. The intervening volumes discuss each requirement of the civil, criminal and ritual law of Israel.)

Maimonides, Moses (*c*.1190) *Dalalat al-Ha'irin (Moreh Nevukhim, Guide to the Perplexed)*, ed. S. Munk, *Le Guide des Égarés*, Arabic text, critically edited, with annotated French translation, Paris, 1856-66, 3 vols; repr. Osnabrück: Zeller, 1964; trans. S. Pines, with an introductory essay by L. Strauss, *The Guide of the Perplexed*, Chicago, IL: University of Chicago Press, 1969; *Rambam*, extensive selections from the *Guide* with commentary by L.E. Goodman, New York: Viking, 1976; reissued, Los Angeles, CA: Gee Tee Bee, 1984. (Maimonides' philosophic masterwork, written in Arabic in the form of a letter to a disciple who has confronted the apparent disparities between philosophic/scientific and biblical ideas.)

Maimonides, Moses (before 1204) *Millot ha-Higgayon (On Logic)*, ed. Y. Satnov, with commentary by M. Mendelssohn, Berlin: B. Cohen, 1927.(Maimonides' work on logic.)

Maimonides, Moses (before 1204) *Kitab al-Fara'id (Sefer ha-Mitzvot, Book of the Commandments)*, trans. with notes by C.B. Chavel, *The Commandments (Sefer ha-Mitzvot)*, London and New York: Soncino, 1967. (Maimonides' listing of the 613 commandments traditionally held to be conveyed in the Pentateuch. In keeping with his thematic approach, Maimonides lists first among the 248 positive commandments 'I am the Lord thy God' and first among the negative commandments 'Thout shalt have no other gods before me'. These are the two commandments that were rabbinically said to have been learned from God himself, as Maimonides explains, citing the Babylonian Talmud, Makkot 23 b.)

Maimonides, Moses (before 1204) *Iggerot ha-Rambam (Maimonides' Epistles)*, trans. with notes by A. Halkin and discussions by D. Hartman, *Epistles of Maimonides: Crisis and Leadership*, Philadelphia, PA: Jewish Publication Society, 1993.(Comprises 'The Epistle on Martyrdom', 'The Epistle to Yemen' and 'Essay on the Resurrection'.)

Maine de Biran, Pierre-François (1766-1824)

Maine de Biran claimed that the starting point for our understanding of human beings lay in introspective psychology: it was the awareness of willed effort. A proper understanding of the will should be the foundation of all work in psychology, including empirical psychology, as well as in the human sciences in general, which should work together towards a coordinated 'anthropology'. Contrary to the assumptions of associationist psychology, mental facts were essentially relational, and language was a constitutive feature of them, rather than being a secondary device intended to represent them. But conscious mental life arose from and was influenced by a subconscious underlayer which could be studied only by the joint use of physiological and introspective methods. Biran rejected the view that mental states can be reduced to, or are nothing other than, physical states. There was a partial 'symbolic' correspondence between them, which meant that physical accounts and mental accounts could not be translated into each other without loss. Later in his life, though still maintaining the belief that psychology was primary, he held that it was necessary to accommodate questions of metaphysics, morality and religion. He published very little during his lifetime, and many of the 'works' found in editions are (sometimes conjectural) editorial restitutions made from a jumbled mass of much corrected manuscripts. His failure to complete a single work on what the eighteenth century had called the 'Science of Man' (which he said was the greatest interest of his entire life) reflects the times: this eighteenth-century project was fragmenting into the multiplicity of human sciences which were emerging as the nineteenth century came. But his insistence on the primacy of the will remains a major challenge for the human sciences of today.

1 Life and works

Pierre-François Gont(h)ier de Biran, French philosopher and public figure, was born at Bergerac in 1766. His father was a doctor. In 1785, after his schooling in Périgueux, he became a royal guardsman and in 1789 was wounded at the defence of Versailles. Though the Guards were dissolved in 1791, Biran (who by now was called 'Maine', a name acquired from a family estate at his majority) still envisaged a career in the military engineers, but this came to nothing. At the end of 1792, he retired to the estate of Grateloup, near Bergerac. At this time, reading was a main occupation and he wrote mainly notes or meditations, rather than works. He did begin a translation of Beccaria with a commentary and somewhat later a memoir on signs. But both these works were left incomplete, setting a pattern repeated throughout his life of intellectual work only sometimes carried to the point of completion.

Gouhier (1948) said of him that 'he was a one-book man - but he never wrote the book'. This book would have been an attempt to fulfil the eighteenth-century project of a 'Science of Man', and he worked at it constantly, once calling it 'the greatest interest of my entire life'. In earlier stages, his attention was focused on psychological topics. His memoir on habit (*Mémoire sur l'influence de l'habitude sur la faculté de penser*, 1803) received a prize from the Institut de France in 1802, and another reflecting the conception of mental science held by the *idéologues* (*Mémoire sur la décomposition de la pensée*, 1804) was awarded the prize in 1805. Publication of this work was stopped at the page-proof stage for mysterious reasons. A memoir on the data immediately present to consciousness (*De l'aperception immédiate*, 1807), replying to a question set by the Academy of Berlin, was awarded a prize in 1807. There followed a series of memoirs on much more specific topics delivered to the Medical Society of Bergerac, which Biran founded, the first on unconscious perception, the second on phrenology, and the third on sleep, dreams and somnambulism. Biran then returned to larger-scale work, with the memoir on the relations between body and mind (*Mémoire sur les rapports du physique et du moral de l'homme*, 1811), submitted to the Royal Academy of Copenhagen, which awarded him the first prize in 1811. In the same year, he signed a contract with a Paris publisher for the publication of revised versions of the memoirs of Berlin and Copenhagen. But he quickly changed his mind, speaking now of a single 'large work'. We know that he regarded this in 1811-12 as 'almost finished'. It concerned the foundations of psychology and its relations to the natural sciences (*Essai sur les fondements de la psychologie, et sur ses rapports avec l'étude de la nature*). But Biran came to think that metaphysical questions of a kind which he formerly disqualified now needed to be treated. This already emerges in a work allied in subject matter to the *Essai* (*Les rapports des sciences naturelles avec la psychologie*), which may have arisen as a reworking of the second part of the *Essai* and may be dated to around 1814. Within a year or two, Biran began to take a much stronger interest than before in questions to do with the nature of morality, and this further extension of interest put completion at a greater distance. In 1819, he

congratulated himself in his diary on not having published ‘anything definitive’ yet, since the spiritual life now needed to be taken into account. In 1820, a specific project intervened. He revised the memoir of Copenhagen for the use of a doctor, Antoine-Athanase Royer Collard, who had consulted him in connection with a course on insanity (*aliénation mentale*) which Royer Collard was to give in the asylum of Charenton in the following year. At the same time, he signed another contract with the same publisher as before for the publication of this revised work, together with the memoir of Berlin, thereby reinstating the plan of ten years earlier. But the publication did not take place, and in 1822 Biran wrote in his diary of going back to his manuscripts and making a work from them which could shortly be published. Among his last attempts at this was a work on ‘anthropology’ in the broadest sense, with the title *Nouveaux essais d’anthropologie* (1823), now making explicit in the title itself the nature of Biran’s ambition; but he died in 1824 without fulfilling his lifelong goal.

2 Problems of the manuscript tradition

The many thousands of surviving folios, often much corrected, present a fascinating spectacle of a mind at work, and a headache for subsequent editors, one of whom wrote in exasperation a generation after Biran’s death of this ‘atrocious scribble’ (‘affreux barbouillage’). The first editor was Victor Cousin (delegated by Biran’s literary executor). He was careless and unscholarly, publishing only four volumes. The second initiative came from François-Marc Louis Naville, a Protestant pastor from Geneva who had met and admired Biran, and who was helped by his son Ernest. They collected about 12,000 pages of manuscript, and Ernest wrote ‘what a task to bring light into this chaos!’. They did a considerable amount of work, recruiting various helpers, and published a version of Biran’s *Essai sur les fondements de la psychologie*. The third editor was Pierre Tisserand, who produced between 1920 and 1949 an edition of Biran’s works in fourteen volumes. Though incomplete and not very scholarly, it made available for the first time a wide and representative collection of texts. Henri Gouhier produced an edition of the philosopher’s diaries between 1954 and 1957. Finally, a more scholarly thirteen-part edition (consisting of seventeen volumes) of the collected works was started in 1984, under the direction of François Azouvi. This edition, for the first time, makes it sufficiently clear to the reader that many of the ‘works’ of Biran were never regarded by him as complete, and that texts have often had to be established by editorial conjecture.

Why Biran completed (and published) so little has been a subject of discussion. A simple answer is that he was too busy with other things. He led an active public life, holding regional and national offices during the revolutionary period, under the consulate of Bonaparte, under the Empire of Napoleon and after the Restoration of the monarchy. Yet this answer seems too simple. Voutsinas diagnosed a deep narcissism in Biran: he avoided publication since he feared the wound of his work not being esteemed. Despite the somewhat obsessive character of Biran’s constant revisions, additions, deletions and reorderings, it may be more enlightening to place his work in its broader intellectual context. For the ‘Science of Man’ was already being fragmented. Biran was thinking about these questions during the birth-pangs of neurophysiology, empirical psychology, social anthropology, economics, political science, linguistics and so on. He was well aware that his project demanded some way of coordinating all these emerging disciplines. He himself made a serious study of some of them. We also find attempts at tabulation. The core should be a reflective psychology which would recognize the will in a way which the British empiricists and their successors had failed to do, and the multiple empirical disciplines studying human nature should be related to and should depend upon this core. But he was never satisfied with his own attempts at seeing how they should fit together. In short, he was pursuing an objective which ran against the temper of the times. Arguably, he was trying to complete a task which, by its nature, could never be completed.

3 The mature position

Biran’s philosophical work stands at a time of transition from the certainties of classical thought. Its character and content permit it to be seen in the context of the meditative tradition of such as Montaigne and Pascal, a tradition which gives prominence to the intimate workings of one’s own mind. This is clear not only from the philosopher’s personal diaries, but also in the central role which he gives to introspection or reflection in his mature theory. Those who see him in this light regard him as part of a lineage which leads to late nineteenth-century French ‘spiritualism’, illustrated by authors like Ravaisson. On the other hand, Biran allies himself strongly with the eighteenth-century empiricist tradition illustrated by authors like David Hartley, Condillac and Charles Bonnet. This emerges not only from his own avowals, but also from his account of the mind which, though diverging from those of his predecessors, is nevertheless clearly a successor to them. It is also

associated with Biran's detailed interest in a variety of fields of empirical study, attested both by the contents of his library, and by the references made in his works. He was interested in physiology, psychiatry, penology, experimental psychology, hypnotism, linguistics, phrenology, ethnography, medicine, pedagogy. In the latter case, it may be noted that he corresponded with Pestalozzi, and appointed one of Pestalozzi's pupils to establish and run a school on Pestalozzian principles in Bergerac (see Education, history of philosophy of §8). It would be insufficient however to give Biran only this double lineage, from the empiricist and the meditative traditions, for he also took an interest in the rationalists, writing on Leibniz. In addition, he read and reckoned with Kant.

It is the works of the first decade of the nineteenth century, culminating in the *Essai*, which develop the position in and about psychology for which Biran is especially known. He accepted what was regarded as a commonplace, that John Locke was the pioneer of mental science. But he held that Locke had made a number of crucial errors. Locke was right to hold reflection to be one of the two sources of knowledge, but wrong to think that it consisted in awareness of 'ideas' (a term newly adapted to mean 'mental representations'). This was to give rise to an essentially passive model of the mind. Perception became the simple reception of data, and action would be either the mechanical result of reception of such data (together with any internal mechanisms at work), or an arbitrary event mysteriously outside the world of causality (see Perception). This view gave rise to a series of problems which Biran thought that no one could answer, or had answered (including Kant). He held that the primary datum of consciousness was the awareness of willed effort (and, in particular, muscular effort) (see Action §4).

The inability of classical empiricism to give an adequate account of the will was illustrated by Hume's claim that the will is 'nothing but *the internal impression we…are conscious of, when we knowingly give rise to any new motion of our body*'. The circularity of this account is frequently criticized by Biran, who insists that what is given to consciousness is essentially relational. An example of a primary fact would be the awareness of raising one's arm. This cannot properly be decomposed into two elements - awareness of a volition and awareness of the arm going up - for then the relation will escape us. 'The inner sense has no object.' What is given is a *fact*, not an object. Of course, we can express our understanding of the fact by referring to the terms of a relation; but the relation is prior to these terms. When I raise my arm, the relation already exists in the effort exerted. It is not that there are two successive components of the experience, either of which might exist without the other.

It may seem that problems arise here. Is there not a causal process capable of empirical study, which consists of successive events in the nervous system which result in the arm going up? Biran conceded this: indeed, he took an active interest in physiology. But he rejected the reductionist view of mental events (see Reductionism in the philosophy of mind). The relation between the awareness of raising one's arm and the physiological story was, he said, 'symbolic'. That is, the one story corresponded systematically but only partially to the other. Neither could be translated into the other without loss.

But if I can be aware of raising my arm, it seems that this presupposes knowledge. I must know that it is my arm that I am raising. This leads to another important difference between Biran and Locke. For Locke thought that ideas were prior to language, and that the function of language was simply to communicate them. Biran, by contrast, held that ideas could not exist without language. Thus a first deliberate raising of the arm is itself the birth of language, since it must bring into being the awareness of the arm. In so far as the movement itself expresses this awareness, it is a sign in the making.

But how can some creatures raise themselves by their bootstraps into a conscious life? Here, Biran departs both from the rationalist and from the empiricist traditions. For he maintains the existence of a passive underlayer of our experience, a great range of affective states which are capable of being drawn up into our conscious life, and which influence it. His interest in this is evidenced not only in his diaries, but also in his philosophical writings, where he discusses at length phenomena such as dreams. There was 'an inner New World to be discovered some day by a Columbus of metaphysics' (*Maine de Biran: Journal*, vol. 1: 176). Physiology and introspection would be needed to 'plunge into the underground caverns of the soul' (*Maine de Biran: Journal*, vol. 1: 240).

These, then, are the main features of Biran's mature position. The awareness of willed effort, a new distinction between passive and active, the crucial role of language, the relational nature of mental phenomena.

4 Later views

While elaborating these views, Biran usually held on to the rejection of 'metaphysics'; but he found increasingly

that questions about the 'primitive facts' could not be properly treated without approaching metaphysical, moral and religious questions. His attempts at dealing with these questions can be seen in the generally more fragmentary works of the last decade of his life.

Near the end of his life, Biran reviewed what he had been doing in his diary, saying that he had come to:

> scorn everything that had previously been my main concern, and to which I had attached some importance and some glory, and I reproached myself for spending my life in erecting a mere scaffold…. However, giving today the chief importance to man's relations with God and with the society of his fellows, I still think that a thorough knowledge of the relations of the *self*…with the concrete person must precede in order of time or study all theoretical or practical research on these two first relations; it is experimental *psychology*, or a science at first purely reflective, that should lead us in due order to the determination of our moral relations with our fellows, and our religious ones with the infinite and higher being…
>
> (*Maine de Biran: Journal*, vol. II: 376)

Biran's partial disillusionment with his own work must be taken seriously: it plays a part in understanding why he completed so little. Yet it opened many very different paths to the future. His claim that mental states are essentially relational ('rien n'est dans la conscience qu'à titre de rapport') prefigures phenomenology (see Phenomenology, epistemic issues in). His claim that there is an internal relation between language and ideas prefigures contemporary critiques by analytic philosophers of the older empiricist tradition. His work coincided with and influenced the early development of empirical psychology. His meditative style prefigures French spiritualism. His claim that there is a new world of the unconscious to be explored by some Columbus versed in physiology and introspection prefigures Freud. And these are not merely points of historical interest. For the central role which he gives to the will, and the way in which he pursues it, are of great current importance, given that late twentieth-century debates about the nature of the mind, including those concerning the development of cognitive science, still often make assumptions which Biran decisively challenged two centuries earlier.

F.C.T. MOORE

List of works

Most of the works of Maine de Biran were not published during his lifetime, and some were published for the first time more than a century and a half after his death.

Maine de Biran, P. F. (1766-1824) *Œuvres de Maine de Biran*, ed. F. Azouvi, Paris: Vrin, 1984-, 13 vols.(The most complete collection of Maine de Biran's works.)

(1766-1824) *Œuvres de Maine de Biran*, ed. P. Tisserand, Paris: Alcan and Presses Universitaires de France, 14 vols, 1920-49.(This was the first attempt at a comprehensive edition of the works of Biran. It is useful but unscholarly.)

(1766-1824) *Maine de Biran: Journal*, ed. H. Gouhier. Neuchâtel: Éditions de la Baconnière, 3 vols.(A valuable edition of most of Biran's surviving diaries. It does not include some 'private' materials which the Naville family in Geneva considered that they could not release, even many years after the death of Biran's last surviving blood relative.)

(1803) *Mémoire sur l'influence de l'habitude sur la faculté de penser*, Paris: Henrichs; trans. M.D. Boehm, *The influence of habit on the faculty of thinking*, Westport, CT: Greenwood Press, 1970.(A discussion of habit and thought.)

(1807) *De l'aperception immédiate (On immediate awareness)*; repr. ed. J. Echeverria, *Maine de Biran: de l'aperception immédiate (mémoire de Berlin 1807)*, Paris: Vrin, 1963.(A work which emphasizes the priority of phenomenology in the 'study of man'.)

Major, John (1467-1550)

John Major was one of the last great logicians of the Middle Ages. Scottish in origin but Parisian by training, he continued the doctrines and the mode of thinking of fourteenth-century masters like John Buridan and William of Ockham. Using a resolutely nominalist approach, he developed a logic centred on the analysis of terms and their properties, and he applied this method of analysis to discourse in physics and theology. Although he came to oppose excessive dependence on logical subtlety in theology and maintained the authority of Holy Scripture, Major's work was stubbornly independent of the growing influence of humanism in Europe. Later, he would be regarded as representative of the heavily criticized 'scholastic spirit', being referred to disparagingly by Rabelais as well as by later historians such as Villoslada (1938), but at the beginning of the sixteenth century, his teaching influenced an entire generation of students in the fields of logic, physics and theology.

1 Life

John Major (or Mair) was born in 1467 at Gleghornie near Haddington in Scotland. He began his studies at Haddington, and after a period at Cambridge, went to Paris. He received his MA in 1494, and in 1495 began to teach as a regent master at the College of Montaigu. In 1506 he became a Doctor of Theology. In 1518 he returned to Scotland where he was principal of the University of Glasgow, as well as teaching logic and theology. From 1523 to 1526 he taught logic and theology at the University of St Andrews. Returning to Paris in 1526, he re-edited his works on logic, as well as publishing commentaries on Aristotle's *Physics* (1526) and *Nicomachean Ethics* (1530), and on the four Gospels (1529). In 1533 he became Provost of St Salvator's College at St Andrews, and remained there until his death in 1550.

2 Logic

Although in the last period of his life at St Andrews Major was regarded as a great authority in theology, he first became famous as a logician. Between 1499 and 1506 he published a large number of logical works, later published as a collection. These works included commentaries on Aristotle and on Peter of Spain, treatises on terms and their properties, on exponibles, consequences, insolubles and obligations (see Logic, medieval).

John Major was trained by the masters who had taken part in the revival of nominalism in the last twenty-five years of the fifteenth century, especially Thomas Bricot, who edited the logic of John Buridan (§2). John Major himself edited John Dorp's early fifteenth-century commentary on Buridan in 1504, and he also edited the logic of the young Spaniard Jerónimo Pardo (d. 1502 or 1505). In his own logical works, his approach was that of a terminist. He accorded a central place to the study of the properties of terms in propositions, particularly their different types of reference, a subject which was thought to be indispensable for avoiding errors of reasoning. This approach goes back to the great synthesizers of the thirteenth century, especially Peter of Spain who was the favourite reference point for the Parisian masters, but it culminated at Paris with the work of John Buridan who placed the study of terms in a nominalist context. In this Major remained faithful to Buridan, often referring to and explicitly adopting 'the solution of the nominalists'.

Major's logic presupposes a theory of spoken and conceptual signs which owed a great deal to William of Ockham (§§6-7). In his treatises on terms, John Major assumed the fundamental presupposition of late medieval logico-linguistic analysis: a term is a sign, and as a logico-linguistic sign, it can only be contemplated in the context of a general semiotic theory. Having defined a sign generally as that which is taken in place of a thing, Major departed from Buridan to assume a position closer to that of Ockham or Albert of Saxony. For him, a spoken sign refers in a proper and primary way to a thing and not, as Buridan had held, to a concept. It is none the less necessary to take into account the properly conceptual components of signification, and so John Major gave a very detailed analysis of the different types of referential relation between the word, the concept, and the thing signified. In this context, he gave a long analysis of the *sophisma* or puzzle case, *debeo tibi equum* ('I owe you a horse'), explaining the different positions which had become standard, namely those of William of Ockham, William Heytesbury, and the one Major preferred, that of John Buridan. This involves distinguishing between the contexts in which a thing is owed under a certain description (the 'appellation of reason'), and those contexts in which direct reference is made to a particular object.

There were very lively debates during this period about the structure of mental language, and John Major developed a theory of mental language close to that of Pierre d'Ailly (see Ailly, P. d'), in which signifying, thinking and representing have a tendency to be assimilated to one another. Following an idea due to Gregory of Rimini, Major admitted that there were two types of mental language, one of which is the image of spoken language, while the other forms mental language properly so-called. He criticized Ockham's view that synonymy as well as some accidental characteristics, such as grammatical gender, could form no part of mental language.

John Major is a witness to the continued life and capacity for innovation of logic at the University of Paris at the beginning of the sixteenth century. He sometimes shows a tendency to wordiness, and in his hands theories become over-refined and over-complicated. However, this complication primarily shows his desire to take into account the difficulties which had become apparent in the course of the two previous centuries, while continuing to make use of terminist and nominalist principles of analysis.

3 Natural philosophy, theology and history

In his commentary on the *Physics* of Aristotle (see Aristotle §8), John Major followed the initiatives of John Buridan (§4) and Marsilius of Inghen (§3) by reformulating problems of natural philosophy on the basis of an analysis of propositions. At the same time, he showed an interest in gathering observations of natural phenomena. In his treatise *De l'infini (On the Infinite)*, added to his logical works in 1506, he took up the distinction between categorematic and syncategorematic senses of the term 'infinite' which had been popularized by Buridan, and he defended the existence of an actual infinite (see Natural philosophy, medieval).

John Major was also a theologian. His commentary on the *Sentences* of Peter Lombard, published in various versions from 1509, was considered by the humanists as representative of a theology which used logic too broadly, introduced too many properly philosophical considerations, and made too regular appeal to Aristotle and Averroes (see Ibn Rushd §§2, 5). It is true that Major, who relied heavily on the commentary by Gregory of Rimini did, like Gregory, include a great deal of logic and philosophy in his theological discussion. None the less, he recommended a moderate attitude on this point. He affirmed the primacy of Holy Scripture, and criticized the excessive use of dialectical subtleties in the study of Scripture. He himself distinguished scholastic theology from positive theology, by which he seems to have meant the more legalistic and moralistic developments of religious teaching.

In religion Major seems to have been animated by the desire to reconcile orthodoxy with the critical approach of nominalism. He regretted the fact that some of his students turned towards the Reformation, and for his part he defended fidelity to dogma and submission to the Catholic Church. In his *In Mattheum ad literam expositio (Literal Exposition of Matthew)* (1518), and then in his commentary on the four Gospels (In quator evangelia expositiones) (1529), he firmly defended the Roman Catholic Church against the theories of Wyclif, Hus and Luther.

In his politico-ecclesiastical works, however, he showed the influence of the Gallican and conciliarist traditions. He limited the power of the Pope in temporal matters, and above all he defended the superiority of church councils over the Pope on the grounds that the fullness of power resides in the church itself, as represented by a council (see Political philosophy, history of §§4, 8).

His *History of Greater Britain*, published in 1521, studies the history of Scotland as parallel to the history of England, and recommends a bringing together of the two kingdoms. The work is written in a critical manner, rejecting a number of traditional stories.

4 Influence

Major's teaching gave birth to a whole school. His pupils (the Spaniards Luis and Antonio Coronel, Gaspar Lax, the Scotsmen Robert Caubraith, David Cranston, George Lokert, the Belgian Peter of Brussels and John Dullaert, among others) carried on the teaching they had received at Montaigu. While in theology some of them, such as Patrick Hamilton (who was burned for heresy at St Andrews in 1527) and the famous reformer John Knox, embraced Protestantism, in logic most were faithful to nominalism. However, the intellectual climate was to change, especially in Paris, becoming hostile to logical subtleties. Not only did interest develop in languages and rhetoric, but polemical texts called into question the very principles of the logical and scientific developments of

the preceding centuries. The work of John Major was done just before this break in tradition, and his merit is that he assured the last hours of glory for the old forms of thought at the University of Paris, with a force that allowed it to continue for a while in Scotland and in Spain.

Malebranche, Nicolas (1638-1715)

Nicolas Malebranche (1638-1715), a French Catholic theologian, was the most important Cartesian philosopher of the second half of the seventeenth century. His philosophical system was a grand synthesis of the thought of his two intellectual mentors: Augustine and Descartes. His most important work, De la recherche de la vérité (The Search After Truth), is a wide-ranging opus that covers various topics in metaphysics, epistemology, ethics, physics, the physiology of cognition, and philosophical theology. It was both admired and criticized by many of the most celebrated thinkers of the period (including Leibniz, Arnauld and Locke), and was the focus of several fierce and time-consuming public debates. Malebranche's philosophical reputation rests mainly on three doctrines. Occasionalism - of which he is the most systematic and famous exponent - is a theory of causation according to which God is the only genuine causal agent in the universe; all physical and mental events in nature are merely 'occasions' for God to exercise his necessarily efficacious power. In the doctrine known as 'vision in God', Malebranche argues that the representational ideas that function in human knowledge and perception are, in fact, the ideas in God's understanding, the eternal archetypes or essences of things. And in his theodicy, Malebranche justifies God's ways and explains the existence of evil and sin in the world by appealing to the simplicity and universality of the laws of nature and grace that God has established and is compelled to follow. In all three doctrines, Malebranche's overwhelming concern is to demonstrate the essential and active role of God in every aspect - material, cognitive and moral - of the universe.

1 Life and works

Nicolas Malebranche was born in Paris on 6 August 1638, one of the many children of Catherine de Lauzon and Nicolas Malebranche, a royal secretary. Because of a malformation of the spine which caused lifelong pain, he was kept at home for his education, under the direction of his mother, until the age of sixteen. In 1656, he graduated from the Collège de la Marche. The education he received there, and from three years studying theology at the Sorbonne, was heavily laden with Aristotelianism, and it left Malebranche highly dissatisfied. After rejecting the offer of a canonry at Notre-Dame de Paris, Malebranche entered the Oratory in 1660 and was ordained in 1664.

His four years in the Oratory proved to be of great intellectual consequence. While studying the Bible, ecclesiastical history and Hebrew, Malebranche, like other Oratorians, immersed himself in the writings of Augustine. There were also Cartesians among his teachers, who introduced him to the doctrines of Descartes. He did not read any of Descartes' works, however, until 1664 when he happened upon a copy of Descartes' *Treatise on Man* (*L'homme*) in a bookstall. The event was life-changing: according to his biographer, Father André, the joy of becoming acquainted with so many discoveries 'caused him such palpitations of the heart that he had to stop reading in order to recover his breath'. Malebranche devoted the next ten years of his life to studying mathematics and philosophy. He was particularly taken by Descartes' critique of the Aristotelian philosophy that he had earlier found so stultifying and sterile (see Medieval philosophy).

Those ten years of study culminated in the publication in 1674-5 of *De la recherche de la vérité (The Search After Truth)*, Malebranche's first and most ambitious work and a synthesis of the systems of Augustine and Descartes. Malebranche's stated goal in the *Recherche* is to investigate the sources of human error and to direct us towards the clear and distinct perception of truth - truth about ourselves, about the world around us and about God. His motives are deeply theological, and he is ultimately concerned to demonstrate the essential and active role of God in every aspect - material, cognitive and moral - of the created world. The *Recherche*, quickly supplemented by seventeen *Eclaircissements*, contains early but solidly-argued presentations of Malebranche's three most famous doctrines: the vision in God, occasionalism and his theodicy.

While the Abbé Simon Foucher, canon of Sainte Chapelle of Dijon, was the first in a long line of critics of Malebranche's doctrines, the Jansenist theologian and Cartesian philosopher Antoine Arnauld was undoubtedly the harshest and most acute (see Foucher, S.; Arnauld, A. §3). Arnauld approved of the *Recherche* upon first reading it. But when he later learned of Malebranche's views on grace and divine providence - sketchily presented in the *Recherche* but more fully expounded in the *Traité de la Nature et de la Grace (Treatise on Nature and Grace)* in 1680 - he embarked on a detailed critique of the major theses of the *Recherche*. Arnauld's *Des vraies et des fausses idées* (1683), and Malebranche's reply, *Réponse du Père Malebranche au livre des vraies et des*

fausses idées (1684), were only the opening salvos in what would come to be a long, often bitter public battle on both philosophical and (to the participants more importantly) theological matters. Although Arnauld's allies succeeded in having the *Traité* put on the Index Librorum Prohibitorum in 1690 (the *Recherche* was added in 1709), their exchanges - public and private - continued until Arnauld's death in 1694. The debate, one of the great intellectual events of the seventeenth century, attracted the attention of Leibniz, Spinoza, Bayle, Locke, Newton and many others.

After the publication of the *Recherche*, Malebranche turned to a 'justification' of the Catholic religion and morality, presented in suitably Malebranchian terms and published as the *Conversations Chrétiennes* in 1676. This was followed in 1683 by the *Médiations Chrétiennes et Métaphysiques*, which consists of dialogues in which 'the Word' explains and defends Malebranche's system. That same year Malebranche also published his *Traité de Morale* in which he undertakes a rigorous demonstration of a true Christian ethics.

By the mid-1680s, Malebranche was widely regarded as the most important, if highly unorthodox, representative of the Cartesian philosophy. His regular correspondents included Leibniz and the physicist Pierre-Sylvain Régis. With Leibniz he debated the Cartesian account of the laws of motion (Malebranche published his *Traité des lois de la communication du mouvement* in 1692), as well as occasionalism and the nature of causal relations. With Régis, who defended a more orthodox brand of Cartesianism, he discussed natural philosophy and the nature of ideas (see Leibniz, G.W. §11; Régis, P.-S.).

Having been forced in his arguments with Arnauld, Régis and others to clarify, develop and even modify his doctrines, Malebranche decided, at the urging of friends, to compose a treatise in which he would both present an up-to-date and concise picture of his theories and defend them as a proper Augustinian (and Catholic) system. The *Entretiens sur la métaphysique (Dialogues on Metaphysics)* were published in 1688 and were supplemented in 1696 by the *Entretiens sur la mort*, which Malebranche wrote after an illness from which he did not expect to recover. In 1699, he was elected to the Académie Royale des Sciences.

During the last fifteen years of his life, Malebranche remained actively engaged in philosophical, theological, and scientific matters, publishing the *Entretien d'un philosophe chrétien et d'un philosophe chinois, sur l'existence et la nature de Dieu* in 1708 and his *Réflexions sur la prémotion physique* in 1715. He also continued to work on the *Recherche*, producing the sixth edition, the last to appear in his lifetime, in 1712. In June 1715, Malebranche became ill while visiting a friend in Villeneuve St. Georges. He was taken back to the Oratory in Paris, where he died on October 13.

2 Vision in God

Malebranche's system is fundamentally Augustinian, and he was inspired by Descartes' philosophy not just because of the scientific and mathematical discoveries he found there but especially because of its own Augustinian nature. He tried to be as faithful as possible to Augustine's thought while at the same time incorporating into his doctrines what he took to be the important metaphysical and epistemological insights of the new mechanistic science. This is particularly evident in his theory of ideas and account of human knowledge.

Nearly all philosophers in the seventeenth century agreed that perception and knowledge is mediated by immaterial representations immediately present to the mind, after Descartes generally called 'ideas'. There was much disagreement, however, over the origin and ontological status of these ideas: How do ideas become present to the mind? Are ideas 'modifications' of the mind? Are they *acts* of the mind or the *objects* of perception? Malebranche's doctrine of the vision in God was the most unorthodox and controversial theory of ideas in the period. He looked back to the Christian-Platonic and Augustinian model, according to which ideas proper are archetypes or essences in the divine understanding. Human beings have access to these ideas, which serve as the ground of all eternal truths, through a continuous process of illumination that informs their cognitive powers.

Malebranche orients his discussion of ideas and knowledge in the *Recherche* around the problem of error, particularly the errors that arise when we base our judgments on the testimony of the senses and the imagination, rather than on reason and understanding. He relies in his analysis of error on what is probably the most comprehensive and systematic account of the physiology of sense and imagination in the seventeenth century. For example, based upon a detailed investigation into the structure of the eye and the geometry of optics, he argues that our sight does not present to us the extension of external bodies as it is in itself, but rather only as it is in

relation to our body. He describes the eye as a kind of 'natural spectacles', and examines the ways in which the material images conveyed into the brain (and thus the sensory images these stimulate in the soul) are variously affected by the distance between the eyes, the different humours in the eyes, the shape of the crystalline lens and its distance from the retina, and other factors. The difference between sensation and imagination is due simply to the fact that in imagination the tiny fibres in the centre of the brain are agitated not by the impressions made by external objects on the exterior surface of the nerves, but by the flow of the animal spirits initiated by the soul itself. These animal spirits are easily affected by the changing state of the body and by external things, as well as by 'moral' causes (prejudices, 'conditions of living'). The imagination thus represents a second important source of the differences between minds and how things are represented to them. Malebranche's goal in highlighting how the senses and the imagination 'lead us into error' is to warn us not to allow their images to serve as a basis for judgment about the truth of things. We should rely, rather, on the testimony of reason and the perfect evidence of clear and distinct ideas.

Malebranche's account of the nature of ideas is grounded in the basic dualist framework of Cartesian ontology. Mind, or thinking substance, is unextended thought, and has absolutely nothing in common with matter, defined as extension. A material body has only the mathematical properties of shape, size, divisibility and mobility. All other sensible qualities - colour, heat, cold, taste, odour and so on - are really only sensations in the mind, mental modifications occasioned by external material objects. While such sensations may indicate to us the presence of bodies to our own body, they cannot provide us with clear and distinct knowledge of those bodies. Sensations can only inform us of what is presently taking place in our own minds; they have no representational value with respect to the external world. Malebranche claims, however, that in addition to our own inner sensations we have access to representative ideas. Ideas, unlike qualitative sensations, have a clear and distinct representational content - generally of a quantitative nature - and provide us with unambiguous and complete knowledge about objects and their properties. The idea of the square, for example, presents with perfect evidence all the information needed for full knowledge of the geometric properties of squares. On the other hand, the heat one feels when near a fire is simply an obscure sensation that reveals nothing about the nature of fire itself as an extended reality. Malebranche's ideas are pure concepts, and their content has no sensory component whatsoever. They just are the logical essences of things or kinds. His epistemological distinction between ideas and sensations derives from Descartes' distinction between clear and distinct ideas and obscure, confused ideas. It roughly corresponds to the distinction made famous by Boyle and Locke between primary quality ideas and secondary quality ideas (see Boyle, R.; Descartes, R. §8; Locke, J. §4).

This epistemological difference between ideas and sensations is, for Malebranche, grounded in an ontological one. While sensations are mental, ideas are not. Representative ideas are 'present to the mind', but they are not modifications of the mind's substance. (Their presence is what allows them to represent extended beings to the mind.) Rather, they are in God, and finite minds have access to them because God wills to reveal them to those minds, all of which exist in a perpetual union with God. That ideas do not belong to the mind becomes clear from the fact that some of our ideas are infinite, and it is impossible for a finite mind to have an infinite modification. Likewise, our ideas are all general - they only become particular or specific when combined with some sensory components - and a particular substance such as the mind cannot have a modification that is general.

Ideas function in all of the mind's cognitive activities; most importantly, in conception and perception. In conception, the mind apprehends a pure idea by itself, without any sensations to particularize the experience (for example, conceiving a geometric circle). In perception, ideas are present but are accompanied by various sensory elements. Thus, when we perceive the sun, the pure idea of a geometric circle is accompanied by colour (yellow) and heat sensations.

Malebranche offers two kinds of argument to demonstrate that representative ideas are required for knowledge and perception. First, he argues that there is generally an unbridgeable distance between the mind and its objects. He sometimes appears to mean this literally, and to be relying on the fact that the mind is not locally present to the external bodies it knows and sees, and that in cognition it is neither the case that objects travel to the mind or that the mind leaves the body to 'travel across the great spaces' that separate it from its objects. His more considered intention, however, is probably to draw our attention to the metaphysical, rather than the physical gulf that separates mind from matter: bodies, being extended, cannot be united with, and thus present to, the unextended mind in the way required for direct cognitive acquaintance. Thus, what is required are intermediary entities that

can both represent extended bodies and be immediately present to the mind: ideas.

Second, it is often the case that we have a perceptual experience of an object when in fact the object itself does not actually exist (for example, in hallucinations and dreams). But Malebranche insists upon the truth of the principle of intentionality, or the claim that every perception must be object-directed - ‘to perceive is to perceive something’ (see Intentionality). As Malebranche understands this principle, every perception must be the direct and immediate apprehension of some really present object. As the illusory cases illustrate, however, the intentional objects of the mind cannot be really existing material bodies; for if they were, we could never have perceptual experiences of objects that do not exist. Thus, it must be that we directly apprehend ideas, non-material representations, even though sometimes there is no external body corresponding to the idea.

3 Vision in God (cont.)

Malebranche’s position is that the ideas that function in human perception and knowledge are simply the ideas - the eternal essences and archetypes - in the divine understanding: that ‘we see all things in God’. In the *Recherche* itself, he relies mainly on an argument from elimination. He shows how all other accounts of the source of our ideas - the Scholastic and Epicurean doctrines, various Cartesian theories (innatism, self-production by the soul) - are untenable, thus leaving the vision in God as the only viable alternative (see Epicureanism). But in this work and others, he also marshals more positive considerations in support of his doctrine. His account, he insists, is simpler than any other hypothesis (hence more worthy of God’s ways), and best fosters a proper and pious sense of our ontological and epistemological dependence upon our creator: we as knowers and perceivers are not self-sufficient, no more than we as beings are self-sufficient substances.

In the *Eclaircissements* appended to the *Recherche*, Malebranche’s debt to Augustine becomes more overt. For Augustine, what we see in God are eternal and immutable truths. Truth is, by its nature, changeless, universal and uncreated. Moreover, truth is higher than, and common to, many minds. Hence, it can be nowhere but in the divine reason, in God himself (in Augustine’s words, truth *is* God) (see Augustine §§6-7). For Malebranche, too, truth is necessarily universal, immutable and infinite. But the truths we know just are relations between ideas. Thus, the ideas themselves must be universal, immutable, and infinite. And such ideas can only be those in God’s understanding. The vision in God is the only possible explanation for our common knowledge of necessary truth - we are all similarly united with one universal, infinite Reason, in which we perceive the same ideas.

Malebranche’s doctrine of the vision in God is motivated, then, not just by the problem of how we perceive bodies in the external world - a specifically Cartesian concern - but primarily by the problem of how we have knowledge of eternal truths. And behind it all lies Malebranche’s deep fear of the dangers of scepticism. The vision in God represents for Malebranche the most effective countersceptical strategy available. First, we can be sure that the ideas we apprehend in sense-perception really do represent bodies in the world because these ideas just are the archetypes that served and directed God in creating those bodies. Thus, they cannot fail to reveal the nature of extended things as they are. On the other hand, if ideas were, as many Cartesians insist, merely fleeting and subjective modifications of the soul, there would be no justification for believing that what they represent about bodies in the world really characterizes those bodies. This would seriously undermine the certainty of physics. Second, any sceptical worries about the necessity, universality and objectivity of mathematical and moral knowledge are forestalled by showing that the ideas upon which such knowledge is based are mind-independent (non-subjective) realities, accessible to all knowers in a universal Reason.

To be sure, there are many relevant questions that the doctrine of vision in God cannot, and is not intended to, answer. For example, while the ideas we apprehend in God inform us as to the essences of things, they cannot provide any evidence about the existence of things. Certainty in this regard can only come about through a combination of faith and sensory experience. This is not to say that Malebranche is a sceptic when it comes to the existence of the external world. Although he claims that we cannot have rational and demonstrative certainty about the existence of a world of things, we still have no good reasons to doubt of it, as well as a natural propensity to believe in it. Nor does the vision in God provide us with a clear and distinct idea of the soul, which would make possible a science of the soul as certain as our science of bodies (physics) based on the idea of body. Our knowledge of the soul is limited to the testimony of *sentiment intérieur*, to what we actually experience in consciousness, and Malebranche rejects Descartes’ claim that we know the soul as well as (or even better than) the body.

The vision in God is a systematic attempt to combine the doctrine of divine illumination that Malebranche found in Augustine with a somewhat deviant Cartesian metaphysics and philosophy of mind. The theory is deeply Augustinian in inspiration, but is geared also to answer certain epistemological questions that really only arise in the seventeenth century.

As Malebranche’s contemporary critics were quick to point out, the doctrine was fraught with ambiguities and inconsistencies. For example, if there is a single immutable idea in God for each object or kind of object he created, how is it that we perceive change and motion in extended things? In the *Eclaircissements* Malebranche denies that he ever meant that there is a plurality of individual, discrete ideas in God. He insists that there is in God an ‘infinite intelligible extension’, and that by applying our minds to this extension in various ways we apprehend representations of different extended bodies in different states of being.

Foucher, in one of his criticisms of Malebranche, focused on the ontological status of ideas. If ideas are spiritual, but are not substances, then they must be modifications of some spiritual substance. Malebranche denies that they are (he insists that they are neither modifications of our minds nor of the divine substance), but then what else can they be? And if they are not ‘ways of being’ of our minds, then they must be as external to our minds as anything else and not ‘present’ to the mind in the manner required for direct cognition. Foucher also asks how immaterial ideas could possibly represent material bodies that they do not resemble (see Foucher, S. §3).

Arnauld argued that the whole notion of ideas as representative beings, distinct from the mind’s perceptions and which are in fact the mind’s objects in perception, is false and even incoherent. Ideas, Arnauld insisted, are not distinguished from the mental acts (he calls them *perceptions*) which represent objects to the mind but are not themselves distinct objects. He claims that Malebranche’s theory, far from explaining how we perceive bodies external to us, actually demonstrates that we never perceive such bodies, and that the mind is surrounded by a ‘palace of ideas’ beyond which it has no cognitive access. Arnauld also focused in his attack on Malebranche’s doctrine of the infinite intelligible extension, and wonders how Malebranche can avoid the charge of materialism, of having placed extension really (that is, ‘formally’) in God and thus making God himself extended (see Arnauld, A. §3). This point is taken up in Spinozistic terms by Dortuous de Mairan, a young man whom Malebranche had once tutored. Mairan was impressed by Spinoza, and he challenged Malebranche both to refute Spinoza’s arguments and to show how the relationship between the infinite intelligible extension in God and the material extension of bodies differs from the substance/affection (or mode) relationship that for Spinoza characterizes the relationship between infinite extension and particular bodies (see Spinoza, B. §§2-3).

4 Occasionalism

Just as the doctrine of the vision in God demonstrates the epistemological dependence that we as knowers have upon God, so the causal doctrine of occasionalism demonstrates the ontological dependence that we and *all* beings have upon an omnipotent God (see Occasionalism). Nothing, it claims, exists or happens in the universe that is not a direct and immediate effect of the divine will. Although occasionalism has its ancestry in certain medieval Islamic, Jewish and Christian theories of causation and divine omnipotence, especially the voluntarist tradition (see Al-Ghazali; Damian, P.), as well as in Descartes’ metaphysics; and while there were others before Malebranche who were, to one degree or another, occasionalists (see Clauberg, J.; Cordemoy, G. de; Geulincx, A.; La Forge, L. de), Malebranche was the first to argue systematically for a thoroughgoing and rigorous version of the doctrine.

Occasionalism is the doctrine that all finite created entities are absolutely devoid of causal efficacy and that God is the only true causal agent. God is directly, immediately and solely responsible for bringing about all phenomena. When a needle pricks the skin, the physical event is merely an occasion for God to cause the appropriate mental state (pain); a volition in the soul to raise an arm or to think of something is only an occasion for God to cause the arm to rise or the idea to be present to the mind; and the impact of one billiard ball upon another is an occasion for God to move the second ball. In all three contexts - mind-body, mind alone and body-body - God’s ubiquitous causal activity proceeds in accordance with certain general laws, and (except in the case of miracles) he acts only when the requisite material or psychic conditions obtain.

Far from being an *ad hoc* solution to a Cartesian mind-body problem as it has traditionally been portrayed, occasionalism is argued for by Malebranche (and others) from general philosophical considerations of the nature

of causal relations, from an analysis of the Cartesian concept of matter and, perhaps most importantly, from theological premises about the essential ontological relationship between an omnipotent God and the created world that he sustains in existence.

Malebranche's first argument that there are no real causal powers in finite created substances and that God is the sole causal agent, focuses on the motion of bodies. He begins with the causal principle that in order for one thing, *A* (which can be a substance or a state of being of a substance), to count as the cause of another thing, *B*, there must be a necessary connection between the existence of *A* and the existence of *B*. 'A true cause as I understand it is one such that the mind perceives a necessary connection [*liaison nécessaire*] between it and its effects' (1674-5 vol. 2: 316). But we can find no such connection between any two physical events, nor between any human mental event and a corresponding physical event. For example, it is certainly conceivable that one can will to raise one's arm but the arm will not rise. 'When we examine our idea of all finite minds, we do not see any necessary connection between their will and the motion of any body whatsoever. On the contrary, we see that there is none and that there can be none' (1674-5 vol. 2: 313). When we consider God, however, as an infinitely perfect being, we see that there *is* such a necessary connection between the divine will and the motion of bodies, since it is logically impossible that an omnipotent God should will to move a body and it does not move; such is the nature of omnipotence. God, therefore, is the only true cause of the motion of bodies.

Malebranche's second argument is based on the 'inconceivability' that any natural cause, any finite mind or material body, should have 'a force, a power, an efficacy to produce anything' (1674-5 vol. 3: 204). First, an idea of body - that is, the clear and distinct idea of extension - represents it as having only one property: the entirely passive faculty of 'receiving various figures and various movements' (1688: 148). It certainly does not represent body as having any active power. Here Malebranche is drawing out the ramifications of Descartes' conception of matter: a Cartesian material body, *qua* pure extension, is essentially passive and inert, and devoid of any motive force. In fact, such a force or power is perceived as *incompatible* with the notion of extension, since it cannot be reduced to or explained in terms of relations of shape, divisibility and distance. Thus, bodies cannot *act*, whether on minds or other bodies. Second, whatever minimal knowledge I have of my soul does not involve the perception of any power, whether to move the body or even to produce its own ideas. All I perceive through inner consciousness is an actual volition to move my arm upwards, and all I notice in my body is that my arm subsequently rises. But I do not perceive, either by inner consciousness or by reason, any power on the part of the soul by means of which it might effect this motion. It is in this sense that 'those who maintain that creatures have force and power in themselves advance what they do not clearly perceive' (1674-5 vol. 3: 204). Indeed, according to Malebranche, I perceive a general incompatibility between the idea of a created finite being and such a power or productive faculty. Only in my idea of the will of an infinite being do I clearly and distinctly recognize any element of power whatsoever.

The third argument is based on a supposedly intuitive premise which (echoing an argument for occasionalism introduced by Geulincx) sets an epistemic condition on the notion of 'cause': in order to count as the cause of an effect, a thing must know how to bring about that effect. Malebranche then appeals to the evident fact that this condition is not satisfied by our minds in order to show that we do not, in fact, cause those motions that we consider voluntary: 'There is no man who knows what must be done to move one of his fingers by means of animal spirits' (1674-5 vol. 2: 315). This same condition rules out the mind's ability to produce its own ideas. It also rules out, *a fortiori*, the possession of causal efficacy by bodies.

Malebranche's most general argument against real interaction appeals to God's role as creator and sustainer of the universe. The argument - which has its roots in both medieval and Cartesian doctrines - purports to show that it is an 'absolute contradiction' that anything besides God should move a body. God's activity is required not only to create the world, but, since creatures are absolutely dependent on God, to sustain it in existence as well. Indeed, for God there is no essential difference between creating and sustaining: 'If the world subsists, it is because God continues to will that the world exist. On the part of God, the conservation of the creatures is simply their continued creation' (1688: 316). When God conserves/recreates a body, he must recreate it in some particular place and in some relation of distance to other bodies. If God conserves it in the same relative place from moment to moment, it remains at rest; if God conserves it successively in different places, it is in motion. But this means that God is and can be the *only* cause of motion: 'The moving force of a body, then, is simply the efficacy of the volition of God who conserves it successively in different places…. Hence, bodies cannot move one another, and

their encounter or impact is only an occasional cause of the distribution of their motions' (1688: 162). And finite minds are no more causes of motion than bodies are.

Thus, God is the direct and efficacious cause of every event in nature; finite beings are only 'secondary' or 'occasional' causes. Malebranche's doctrine can be seen as embedded within a voluntarist tradition that extends from certain medieval thinkers - many of whom attacked the Aristotelian theory of nature in the name of safeguarding God's omnipotence - up through Descartes (see Voluntarism).

This does not mean that for Malebranche natural philosophy has been reduced to a single theocratic claim. At the level of physics proper, the task of the scientist is still to uncover regularities in nature and formulate the laws that govern the correlations between events. The programme of the mechanical philosophy, to which Malebranche enthusiastically subscribes, remains the same: to discover the hidden mechanisms that underlie observed phenomena and to frame such explanations (referring to secondary causes) solely in terms of matter and motion. What Malebranche's occasionalism does is to give an account of the metaphysical foundations of Cartesian physics. Motion, the primary explanatory element in the new science, must ultimately be grounded in something higher than the passive inert extension of Cartesian bodies; it needs a causal ground in an active power or force. Because a body consists in extension alone, motive force cannot be an inherent property of bodies. Malebranche accordingly - and his account seems to be a logical extension of the role Descartes gives to God as the 'universal and primary cause of motion' (see Descartes, R. §§6, 11) - places the locus of force in the will of God, and bodies behave the way they do because that is how God moves them around, following the laws of nature he has established.

Malebranche did, in fact, use his metaphysics of motion to modify some details of Descartes' physics, particularly the rules governing bodily impact. This led to an extended debate with Leibniz over the laws of motion. In the *Recherche* Malebranche insists, contrary to Descartes, that bodies at rest do not have a force to remain at rest (unlike bodies in motion, which have a force to remain in motion). This conclusion follows directly from his occasionalist account of motion: although God does need to will positively to put a body in motion, he does not need to apply any force to keep it at rest; all he needs to do is will that it continue to exist, that is, recreate it in the same relative place. Thus, the tiniest body in motion will contain more force than the largest body at rest. And this means that three of Descartes' seven rules of impact are wrong. Leibniz, in his general critique of Cartesian physics, praised Malebranche for recognizing Descartes' errors. He insisted, however, that because Malebranche was still wedded to Descartes' conservation law (where what is conserved is quantity of motion, rather than the quantity of motive force that Leibniz proposed), Malebranche has failed to see that *all* except the first of Descartes' rules, along with the new rules he had substituted for the ones he rejected, were wrong (see Leibniz, G.W. §11). In 1692, Malebranche published his *Des lois de la communication des mouvements*, in which he concedes that Leibniz is right about the rules themselves, but continues to maintain the old conservation law. It was not until a letter to Leibniz in 1699 and the 1700 edition of the *Recherche* (which contains a revised version of *Des lois*) that Malebranche admits that Descartes' conservation law is false.

5 Ethics

For Malebranche, God's ubiquitous causal activity does not eliminate freedom of the will in human beings. God is the direct source of an invincible inclination or 'natural motion' in the soul towards good in general. We cannot not will to be happy, and we necessarily love what we 'clearly know and vividly feel' to be good. But it is in our power to allow or to refuse to allow this general determination towards good given to us by God to rest upon one or another of the particular things we believe to be good. All minds, he notes, love God 'by the necessity of their nature', and if they love anything else, it is by a free choice of their will. We sin when, rather than directing the will by a clear and distinct perception of the supreme good to the love of God, we allow it to be directed away from God towards the pleasing but false goods presented to us by our senses.

In the *Traité de morale* (1683b), Malebranche elaborates on just what this love of God involves, providing a fuller account of our ethical duties. Within God, there lies an immutable order or law which God consults when acting. This order is constituted by what Malebranche calls 'relations of perfection', which in turn entail a hierarchy of value among beings. Order dictates, for example, that a beast is more perfect, hence more worthy or 'estimable' than a rock, and a human being more perfect and worthy than a beast. A human being is thus to be treated with more consideration than a horse. Through our 'union with the eternal word, with universal reason' we can have

rational knowledge of order. Our duty, then, consists in ‘submitting ourselves to God’s law, and in following order’. We ought, like God, to regulate our actions and esteem by consulting it. In this way, ‘there is a true and a false, a just and an unjust’ that is binding upon *all* intelligent beings. Malebranche insists that our principal duty and our ‘fundamental and universal virtue’ is to love order and obey its precepts.

6 Philosophical theology

Malebranche’s occasionalism takes on greater importance in the context of his theodicy, or justification of God’s ways in the realms of nature and grace. In his *Traité de la nature et de la grace* (1680), Malebranche undertakes the task of explaining how God’s omnipotence, benevolence and perfection can be reconciled with the persistence of evil and imperfections in the natural world (including human suffering and sin) and with the apparent unfairness and inefficiency in the distribution of divine grace and everlasting happiness.

Our concept of God tells us that God is infinitely wise, good, powerful and perfect. And yet the world which God has created certainly appears to us to be quite imperfect in its details and full of disorders of every variety. As Theodore, Malebranche’s spokesman in the *Entretiens sur la métaphysique*, exclaims, ‘The Universe then is the most perfect that God can make? But really! So many monsters, so many disorders, the great number of impious men - does all this contribute to the perfection of the universe?’ (1688: 211). Aristes, his interlocutor, is led thereby to wonder either about the efficacy of God’s will or the benevolence of God’s intentions.

The resolution of this conundrum, as presented in both the *Entretiens* and the *Traité*, is to be found in the consideration not just of the particular, superficial and obvious details of the universe, but also of the means undertaken to achieve and sustain the whole. God, according to Malebranche, looks not only to the final result of his creative act (that is, to the goodness and perfection of the world *per se*), but also to his work or ways of operation. And the activity or means most expressive of God’s nature are of maximum simplicity, uniformity, fecundity and universality. God does not accomplish by complex means that which can be accomplished by simple means; and God does not execute with many particular volitions that which can be executed by a few general volitions. This holds true even if it means that the world created by God could be spared some imperfections were God to compromise the simplicity and generality of his operations. Thus, the perfection of the world in its details as a product is completely relative to the mode of activity that is most worthy of God. God might increase the absolute perfection of the world, perhaps by decreasing the number of defects or evils therein. But this would entail greater complexity in the divine ways and constant departures from the general laws of nature established at creation.

Thus, the world that God has created is the one of the infinitely many possible worlds that best reconciles perfection of design with simplicity and generality of means of production and conservation. By a number of ‘particular volitions’ - that is, volitions that are *ad hoc* and not occasioned by some prior event in accordance with some law of nature - God could correct deformities of birth, keep fruit from rotting on trees, prevent physical disasters about to occur by the regular course of the laws of nature, and forestall sin and wickedness. But, Malebranche insists, ‘we must be careful not to require constant miracles from God, nor to attribute them to him at every moment’ (1680: 34). God, in other words, acts only by ‘general volitions’ - that is, volitions that are in accordance with some law and whose operation is occasioned by a prior event, as dictated by that law - and the most simple ways.

Similar considerations apply to the problem of grace. A benevolent God wills, with what Malebranche calls a ‘simple volition’, that sinners convert and that all humans should be saved. But clearly not all humans are saved; many are lost. And not all those who are saved appear to be worthy of salvation or ready to receive grace. The anomaly is again explained by the generality of God’s volitions. The distribution of grace is governed by certain general laws willed by God, and the occasional causes responsible for the actual distribution of grace in accordance with those laws are the thoughts and desires in the human soul of Jesus Christ. Because Jesus *qua* human has finite cognitive capacities, he cannot at any given time attend to all the relevant facts about the agent upon whom grace is to be bestowed - for example, whether they are ready to make the best use of it - or actually think of all who deserve to be saved. Thus, as with the distribution of evil and imperfection in the natural world, God *allows* grace to be distributed unevenly and even inequitably by the laws of grace in combination with the occasional causes that activate them.

It was the *Traité*, with its claim that God wills to save *all* humans and the implication that God's volitions are not always efficacious (since not everyone is saved), that initially aroused Arnauld's ire and occasioned his attack on Malebranche's whole system. Arnauld, as a Jansenist, was committed first and foremost to a strong doctrine of predestination and to the efficacy of divine volitions, particularly in the matter of grace. Pierre Bayle rallied to Malebranche's defence on this and other issues, and the pages of Bayle's *Nouvelles de la république des lettres* in the 1680s became an important battleground for the debates instigated by Malebranche's works.

7 Influence

Malebranche's influence in the seventeenth and eighteenth centuries was significant, but subtle and often unacknowledged. There is no question that his contemporaries recognized him as *the* major representative of the Cartesian system, however unorthodox his Cartesianism may have been. Leibniz's arguments against 'the Cartesians', for example, are often directed at Malebranche. And yet, despite his criticisms of occasionalism, Leibniz was himself impressed by Malebranche's discussion of causation and critique of interaction between substances. Moreover, Leibniz's own theodicy and solution to the problem of evil were clearly influenced by what he read in Malebranche. Like Malebranche, Leibniz insists that God in creation chooses from an infinity of possible worlds, and that God pays particular attention not just to the created theatre itself, but especially to its relationship with the laws of nature and grace. Malebranche considers the laws as separate from 'the world', and gives them a higher value. He grants that the world God created may not be, absolutely speaking, the best of all possible worlds, but it is the best that can be done given the absolute simplicity of means God employs. Leibniz, on the other hand, considers the laws and the universe they govern together as 'the world', and insists that the combination *is* the best world overall. But they agree that evil and sin occur because God *allows* them to occur as a result of the ordinary course of nature as governed by the laws God has chosen. They agree that God could diminish the imperfections of the created world, but only by violating the simplicity of the divine ways (as Malebranche would put it), or by detracting from the *overall* optimality of the world (as Leibniz would say). Leibniz even goes so far as to suggest to Malebranche that, in the end, their accounts are the same, although Malebranche disagrees.

Malebranche's influence extended across the Channel (and not just to such overt followers as John Norris). Despite Berkeley's indignant claim that 'there are no principles more fundamentally opposed than his [Malebranche's] and mine', there are obvious echoes of Malebranche's doctrines in Berkeley's works (see Berkeley, G. §2). For example, Berkeley's ideas, like Malebranche's ideas, are not modifications of the finite mind but are independent of it. They are also in the mind of God, since it is 'an infinite spirit who contains and supports' the world of ideas. Similarly, with respect to causation, Berkeley denies that our ideas of bodies provide us with any notion of causal power or efficacy. And while Berkeley departs from Malebranche's doctrine and grants real causal power to the human soul (and thus is not a complete occasionalist), he insists, like Malebranche, that the ordinary course of natural phenomena, the regularities and correspondences in our ideas of things, are the result of the causal activity of the will of a governing spirit, that is, God.

Hume was more forthcoming in acknowledging his debt to Malebranche in his conclusions about causality. His arguments denying that our idea of body affords us any notion of causal power and his insistence that all that experience reveals is a constant conjunction between events seem to come right out of Malebranche's *Recherche*. Both Hume and Malebranche stress the centrality of the concept of necessary connection to our understanding of causation, and both deny that such necessity can be discovered (by reason or experience) between any things in nature. The difference is that Malebranche held that we can perceive a necessary connection between the will of God and any event willed by God, while Hume rejected any such claim.

STEVEN NADLER

List of works

Malebranche, N. (1958-67) *Oeuvres complètes de Malebranche (Complete works of Malebranche)*, ed. A. Robinet, Paris: J. Vrin, 20 vols.(The standard edition of Malebranche's writings. The main philosophical works are in the volumes listed below.)

Malebranche, N. (1674-5) *De la recherche de la vérité*, in *Oeuvres*, vols 1-3, 6th edn, 1712; trans. T. Lennon and P.J. Olscamp as *The Search After Truth/Elucidations of the Search After Truth*, Columbus, OH: Ohio State University Press, 1980. (Malebranche's most important philosophical work. Vol. 3 of the *Oeuvres* contains the

Éclaircissements.)
Malebranche, N. (1676) *Conversations chrétiennes (Christian conversations)*, in *Oeuvres*, vol. 4.(A 'justification' of the Catholic religion and morality.)
Malebranche, N. (1680) *Traité de la nature et de la grace*, in *Oeuvres*, vol. 5; trans. P. Riley as *Treatise on Nature and Grace*, Oxford: Oxford University Press, 1992. (Malebranche's theodicy and account of human freedom.)
Malebranche, N. (1683a) *Méditations chrétiennes et métaphysiques (Christian and metaphysical meditations)*, in *Oeuvres*, vol. 10.(A reworking of his metaphysical and epistemological doctrines including the vision of God.)
Malebranche, N. (1683b) *Traité de morale (Treatise on morality)*, in *Oeuvres*, vol. 11.(A treatise in Christian ethics and human happiness.)
Malebranche, N. (1684-94) *Recueil de toutes les réponses à M. Arnauld (Collection of all the responses to M. Arnauld)*, in *Oeuvres*, vols 6-9.(Contains correspondence related to the Malebranche-Arnauld debate, as well as Malebranche's *Réponse* to Arnauld's *Des vraies et des fausses idées*, and some other pieces.)
Malebranche, N. (1688) *Entretiens sur la métaphysique et sur la religion*, in *Oeuvres*, vol. 12; trans. W. Doney as *Dialogues on Metaphysics*, New York: Abaris, 1980.(A presentation, in dialogue form, of Malebranche's doctrines *c.*1688, after some development since the *Recherche* in the light of various debates.)
Malebranche, N. (1692) *Traité des lois de la communication du mouvement*, in *Oeuvres*, vol. 2. (A critique of Descartes' account of the rule of impact.)
Malebranche, N. (1696) *Entretiens sur la mort*, in *Oeuvres*, vol. 13.(A continuation of the dialogues on metaphysics concentrating on death and the soul.)
Malebranche, N. (1708) *Entretien d'un philosophe chrétien et d'un philosophe chinois (Dialogue between a Christian philosopher and a Chinese philosopher)*, in *Oeuvres*, vol. 15. (Christian apologetics.)
Malebranche, N. (1715) *Réflexions sur la prémotion physique (Reflections on physical premotion)*, in *Oeuvres*, vol. 16.(Malebranche's response to Abbé Boursier on God's action on creatures.)

Mamardashvili, Merab Konstantinovich (1930-90)

Merab Mamardashvili was one of the Soviet Union's most influential thinkers in the fields of phenomenology and philosophy of consciousness. Although he preferred the Socratic genres of the dialogue, interview and philosophical meditation to the abstract rigours of more systematic philosophy, he left substantial published work on Descartes, Hegel, Kant and French literature (especially Proust).

*Mamardashvili began his career as a historian of philosophy, with a series of close readings of Karl Marx. By the 1970s he had evolved his own distinctive style of 'philosophizing out loud', addressing the foundations of European philosophy based on Descartes and Kant, at the core of which was the search for the 'free phenomenon' (*svobodnyi fenomen*) or the 'event of a thought' (*sobytie mysli*). In Kantian fashion, Mamardashvili attended to those a priori conditions of lived experience which govern that moment when reality enters the transcendental realm - but he switched the emphasis: rather than the mental problems presented by the a priori moment, Mamardashvili concentrated on what he called a 'metaphysics of the a posteriori', that is, on the actual event, or advent, of a thought. Perhaps the single motivating question of his life was: 'How is a new thought possible?' Among his many answers, developed in public lectures and interviews during the last twenty years of his life, was the notion that the very processes of thought provoke 'hearing a thought' in another. From this follows his concern with dialogic forms and his interest in the Cartesian dualism of soul and body - not as a necessary truth but as a 'productive tautology' that makes internal reason and a 'grammatical' analysis of thinking possible on a palpable basis.*

1 Life

Mamardashvili was born in Gori, Soviet Georgia (the birthplace of Stalin), to a military family. After residence in Leningrad and Kiev, the family resettled in Tbilisi in 1941, where he finished high school; he then entered the Department of Philosophy at Moscow State University, graduating in 1954 and receiving his candidate's degree (Ph.D.) in 1957. Always more interested in the nature of human consciousness as *experience* rather than as system or theory, Mamardashvili did not immediately attach to an academic institution. After working as editor for the journal *Voprosy filosofii (Questions of Philosophy)*, he spent 1961-6 in Prague as editor of *Problems of Peace and Socialism*; upon his return to Moscow he lost his rights to travel (managing to visit his beloved France only in 1988). At this time Mamardashvili began delivering lectures (or *besedy*, 'conversations', as he preferred to call them) in various institutes to students of philosophy, psychology, pedagogy, theatre and cinematography. In 1970 he defended his doctoral dissertation in Tbilisi; he worked in that city and in Moscow until his sudden death at the age of 60.

Disciples of his thought are very active in post-communist Russia, especially in the Laboratory for Post-Classical Studies (of the Institute of Philosophy, Russian Academy of Sciences), pursuing questions of symbolic consciousness, history of science and theory of creativity. Among his most prominent students are Aleksandr Piatigorskii, Mikhail Ryklin, Anatolii Akhutin andMamardashvili's archivist Iurii Senokosov.

2 Critical works

Mamardashvili's genre was the interview, the lecture series, the roundtable discussion, which enabled what he called '*filosofstvovanie vslukh*', 'philosophizing out loud'. In his meditations on Kant, Mamardashvili defined *filosofstvovanie* as a 'sensual and palpable turn of the soul, a feeling for ideas', which was always prompted by an 'element of life, not of theory' ([1982b] 1991: 150). As one of Mamardashvili's most prolific students, Mikhail Ryklin, has remarked, oral speech for Mamardashvili was like improvisation for a jazz musician: to emerge at all, his most creative ideas needed a live listener present. Mamardashvili did not write 'for the drawer' because, in his words, he 'utterly lacked any consciousness of persecution' and preferred talking to writing (1990a: 178).

3 'Philosophizing' versus 'Russian' philosophy

Mamardashvili did not believe that one could be a 'national philosopher'. He was no partisan of the Russian Religious-Philosophical Renaissance (in this he resembles Pëtr Chaadaev rather than Nikolai Berdiaev or Vladimir Solov'ëv); in his lectures on Proust, he remarked that 'one of the ideas that had ruined Russian culture at the beginning of the century was the theurgical idea, the notion that the world had been created so that life itself could

be constructed like a work of art' (Kruglikov 1994: 111). He charged the radical intelligentsia with '"dirty", littered consciousness and slovenly thinking' (1990a: 132); and even the *Vekhi (Signposts)* opposition, in his opinion, was too partial to endless acts of repentance. Mamardashvili's attitude towards religion was complex. In his 'Besedy o myshlenii' (Conversations about Thinking) (1986-7), discussing the sophisticated forms of French secular and sacred language, he remarked that 'the language of religion is necessary in order to distinguish a person striving towards the good from a [simply] good person' - a distinction that arrives very late in 'infantile cultures' such as the Russian, and when it does (Mamardashvili says, agreeing with Dostoevskii), it goes unnoticed, causes anguish and often generates evil ([1986-7] 1991: 25).

In general we do not think enough about *how we think*, nor about the consequences of an act of thought. Russia was especially deficient in this talent, eager to use words but unwilling to accept results; thus it has been in the 'hellish condition' of a country of 'eternal pregnancy' ([1987] 1990: 372). Descartes and Pushkin were exemplarily honest thinkers in this sense, Mamardashvili believed, as men who became free by accepting responsibility for control over their own words and gestures (Kruglikov 1994: 20-3); Dostoevskii was less so, for, in some of his preconceptions - his odd assumption, for example, that to be poor was *ipso facto* to be simple and honest - he challenged the sensible workings of the mind ([1986-7] 1991: 26). Ideas themselves, in the structure of consciousness, are so 'complex, delicate and multi-layered' that we should 'tremble from fear before the responsibility' of handling them (1990a: 130). As Ryklin sums up his teacher's position: on the one hand, 'in his work, all of philosophy becomes ethics'; on the other, 'ethics itself is presented exclusively in the form of a theory of cognition' (*Voprosy filosofii* (1991) 5: 21).

Mamardashvili did not believe that ideas were ever produced by the 'masses'. For culture is assimilated individually and cannot be collectivized or generalized. By 'culture', Mamardashvili understood not a set of guidelines or fixed values, but rather a 'definitiveness of *form* within which people were capable (and prepared), through their acts, to practise *complexity*' (1990a: 173). Accordingly, Mamardashvili's recurring concerns were individual autonomy; the necessity to keep separate the empirical and the non-empirical worlds (Mamardashvili resisted all utopian and apocalyptic models of history); a more modest societal role for art and the literary word ('art for art's sake' is more democratic, he felt, than prophetic or socially committed art (1990a: 127)); how to achieve 'civilization', the major binding force or grammar uniting highly independent and particularized minds; and, underlying all these concerns, the mechanism of thinking itself.

Mamardashvili's major questions and modes of thought nevertheless reflect the Russian philosophical tradition in three ways. First, like his heroes Descartes and Tolstoi, he directs his insights on consciousness and morality not to academic philosophers but to untrained minds seeking clarification in everyday language. Second, he draws on great literature as primary material for philosophical speculation - and indeed, he sees no firm boundary between art and this type of 'science'. And third, his subject matter is grounded not in formal logic or abstract systems but rather evolved under the inspiration of several exemplary creative figures in European culture: Hegel, Kant, the early Marx, Descartes, Husserl, Proust, Kafka and Mandelstam.

Mamardashvili devoted dozens of 'conversations' to the meaning of philosophy itself. It is not a science, he claimed, nor is it a picture of the world. In an interview near the end of his life (1990), published under the title 'Solitude is my Profession', Mamardashvili defines the philosophical moment as 'a shard from the broken mirror of universal harmony, fallen into the eye or the soul', 'an allegory for the passion of freedom' (Kruglikov 1994: 64). Elsewhere Mamardashvili explains that such freedom is in fact a necessity: for only the rational epiphany of a newly coalesced thought can reverse natural law and move from death to life (otherwise, the cosmos would have long ago contained only inert matter). But this epiphany is not religious; religion elicits from us a worshipful response and we can suspend its acts passively, indefinitely, within a system of faith. Philosophy, on the other hand, is an interval, a 'pause that is essential to the structure of the life of consciousness, essential to human acts'.

Thus philosophy is a place - or an attitude - that we occupy when we have the courage to say 'I do not understand'. It does not judge content (good and evil, right or wrong), and it does not 'fill up'; like moral conscience, it is best defined as a form and a dynamics, an inner reflex that, once stimulated, will *not turn away*; and thus it exists eternally and its problems repeat forever. (Following Socrates, Mamardashvili insists that to exist, philosophy - like virtue - must be accomplished again and again; whereas evil can register its effects by happening only once.) We philosophize when our consciousness is exacerbated by a sudden break or discontinuity between itself and its

surroundings; in order to mend that break we must commit to an effort to think honestly or honourably (*myslit' chestno*). This is extremely difficult to do; and for this reason, Mamardashvili considered Descartes and Kant among the greatest European philosophers.

When Mamardashvili delivered his *Kartezianskie razmyshleniia (Cartesian Meditations)* in Moscow in the winter of 1981, it marked, according to one eyewitness, the rebirth of professional philosophical thought in the Soviet Union. Through the medium of Descartes, these fifteen meditations reintroduced the themes of faith, the possibility of God within a rationalist universe, the 'miracle of individual thought', and the centrality of epistemology to any primary philosophy. In his opening lectures, Mamardashvili declared that 'for thought, the worst enemy is the *past*'; knowing that every mental image becomes more concrete, precise and manageable the less it is actually present, Descartes filled his own 'Meditations' and 'method' with the word 'now'. This was welcome balm to his Soviet audience, weary of Marxist-Leninist surrogates for the present tense. In his final lecture, Mamardashvili gently chided both the Russian tradition of the radical intelligentsia and the revived clichés of Russian religious thought through the sobering lens of Cartesian thinking - with its methodical doubt, its separation of body and spirit, its assumption (and here Mamardashvili also drew on Proust) that too many 'serious conversations' were a 'waste of time' and better worked out in solitude. On Christ's crucifixion, Mamardashvili remarked that

> 'the cross is an ironic reminder to us that we need not herd people into an image, inasmuch as this image, within our heads, is capable of killing. And there are cultures and even whole epochs when people love the dead most of all, because the dead can no longer exit from their own image and thus they speak only that which we speak ourselves'
>
> ([1991] 1993: 341)

4 Contribution to the performing arts and practical aesthetics

This fascination with the rights and possible reconstitution of a genuine *present* lies behind Mamardashvili's interest in the theatre and visual temporal art (he was a frequent lecturer at theatre training institutes); and, as he wrote in *Teatr* magazine in 1989, 'the theatrical stage is a place for the "presence of absent reality"' (1990a: 138). It also permeates his 1982-4 lectures on Proust. Among the major themes in those lectures are the 'indivisibility of presence' (Kruglikov 1994: 114), the nature and degree of energy required to awaken ourselves from habit, and the phenomena of 'aroused attention' and memory. How, indeed, does a 'thought' or a 'desire' start? What does it mean to actualize a part of the past towards this end?

'Spontaneous memory' occurs in us in response to an apparently arbitrary summons. But, Mamardashvili asks, can we *command* ourselves to experience something strongly, to love, to be aroused, to be upset or to be riveted in place? The Proustian moment - being triggered by a present triviality into re-experiencing a profound past reality - Mamardashvili calls the 'zone of helplessness' (Kruglikov 1994: 94). It is a finicky and subtle state. If we try to force it, then the memory-experience is almost always negative: it feels empty, and we feel at a loss. For any mental gesture that does not provide the potential for a free supplement from the present, that is only a forced calling-up of the past, is a void that will be filled with illusion. Mamardashvili interprets the folksaying '*Sviato mesto pusto ne byvaet*' ('A sacred space is never empty') to mean that evil always settles in emptiness; the Good demands fullness, that is, a responsive act from us in return. When this condition is not met, we have negative memory: that which summons us in the absence of an active and sentient present. Mamardashvili concludes that for Proust (and for him), our life is real to the extent that a precious event in it is *created anew by thought* (Kruglikov 1994: 97). Ending one of his lectures on 'What is Philosophy?' with a discussion of Proust's novel, Mamardashvili noted:

> (The text of the novel is the means by which feelings can be experienced.) Not those that *you* experience…but you-as-an-other, recreated, fixed in time and space, posited by a movement of decoding, which does not depend on the chance happenings of life and in which you can establish yourself as a person of fate who controls his own fate. For you there will be no other fate. But that which will be, you already control.
>
> (*Voprosii filosofii* (1991) 5: 10)

Certain general statements can now be made. In Proust - and in philosophy in general - Mamardashvili investigated 'sudden beginnings', or what he called 'surprise': those experiences, thoughts and events that seem to arise 'out of nothing'. Unlike Russian apocalyptic and messianic thinkers (who studied collective ends), and unlike

his senior colleague in the philosophy of consciousness, Bakhtin (who exclusively studied middles), Mamardashvili made a point of studying the miraculous surprise of *individualized beginnings*. Culture itself is defined as that set of specific forms within which individuals could realize increasing complexity.

All true philosophizing has a phenomenological aspect, Mamardashvili taught, although the impulse for his own questioning came not from Husserl but from Marx (in his own words, he moved from Marx to an 'intuition of "bodies", that is, to "structures of palpable agency"' in the world, and then to the 'concrete object-ness of a thought' as the 'living, extra-mental reality of the soul' (1990a: 102)). Mamardashvili was not a political philosopher, nor a social one. He was, rather, a personalist and intentionalist of the sort that has special resonance in a culture like Soviet Russia, so familiar with political abuse and collective utopia: while greatly admiring Kant and considering him not part of that 'epoch of strictly German philosophy, so repulsive to me' ([1982b] 1991: 121), Mamardashvili distrusted the power that moral norms held over an individual and worried about the proper procedures for stitching ourselves into them ('In a broad sense', Mamardashvili writes, 'for Kant, a norm is a grimace, a going to church… Grimaces of the spirit' ([1982b] 1991: 145)). Individual will is integrated into norms, he believed, but all social and spiritual creativity is dependent upon on the participation of 'a sufficient number of adult, non-infantile people who rely on their own individual minds' ([1987] 1990: 374). In a lengthy excursus on memory and its role in the poet Mandelstam's famed '*toska po mirovoi kul'ture*' (longing for world culture), Mamardashvili remarked, again in the spirit of Chaadaev, that Russians have never achieved a secure sense of continuity, of belonging, of having authentic organs of birth ([1986-7] 1991: 40-4); and for this reason, perhaps, Russians are so familiar with the terror at possible non-being which fuels philosophy.

In the late 1980s, Mamardashvili elaborated his 'Principle of the Three Ks': *Karteziia* (Cartesianism, Descartes), Kant and Kafka ([1984b] 1990: 109-12). The Cartesian 'I' asserts its own first-person-singular existence and doubts every other thing. The Kantian 'I' is subordinated to a third-person transcendental point of view; its strength lies in its attention to the real-world conditions and coordinates that shape an act. The Kafkaesque 'I' knows neither first nor third person; it is a zombie, a humanoid without agency functioning in the realm of the absurd. Curiously, Mamardashvili suggested that it was only in the *glasnost'* period - for he did not live to see the end of Soviet communism - that the third, Kafkaesque 'I' was in fact recognized as such on Russian soil: before that time, absurdity was blamed on politics, on Stalinism, and thus explained away not as a spiritual option (which it is) but as a brutal imposition by politics. In laying out his taxonomy of the three types of self, Mamardashvili reveals himself to be an unsentimental phenomenologist in the Stoic vein. 'A philosopher is not surprised at evil, destruction, chaos or disorder, although usually we, people, are surprised at that…. What is surprising and remarkable is that there is good…. Just a tiny island of order in the chaos - that's remarkable' ([1979] 1992: 31).

List of works

Mamardashvili, M.K. (1968) *Formy i soderzhanie myshleniia (The Forms and Content of Thinking)*, Moscow. (Survey of phenomenological and Kantian paradigms for the production of thought; academic in approach.)

Mamardashvili, M.K. (1979) 'O poniatii filosofii' (On the Concept of Philosophy), lecture at Rostov State University, in *Novyi Krug (Kiev)* 1992: 1.(Mamardashvili's discussion of 'two categories of things': those that happen, and those that do not happen, 'by themselves'; the notion of freedom as that which happens 'without choice'; the difference between philosophy and culture.)

Mamardashvili, M.K. (1982a) *Simvol i soznanie (metafizicheskie rassuzhdeniia o soznanii, simvolike i iazyke) (Symbol and Consciousness: Metaphysical Speculations on Consciousness, Symbolic Structures and Language)*, with A. Piatigorskii, Jerusalem.(Non-technical discussion of the structure of consciousness, the sign, the symbol, the natural versus the artificed in language, as part of a search for the epistemological basis for semiotics.)

Mamardashvili, M.K. (1982b) *Kantianskie variiatsii (Kantian Variations)*, lectures delivered in Moscow; fragments published in *Kvintessentsiia: Filosofskii almanakh 1991*, Moscow, 120-57.(An examination of Kant's sentiment that 'a soul overfilled with feelings, and not speech, is the highest of all perfections'; the role of words for Rousseau and of meaning for Kant.)

Mamardashvili, M.K. (1984a) *Klassicheskii i neklassicheskii idealy ratsional'nosti (Classic and Non-Classic Ideals of Rationality)*, Tbilisi. (Investigations of a relatively non-technical nature into the problem of observation, the notion of a phenomenon and its multiple dimensions; and the symbolic element in all rational thought.)

Mamardashvili, M.K. (1984b) 'Soznanie i tsivilizatsii' (Consciousness and Civilization), lecture delivered in Batumi, published in *Kak ya ponimayu filosofiiu (How I Understand Philosophy)*, 1990, 107-21. (Includes Mamardashvili's 'three Ks' as ways of organizing the world: Decartes, Kant and Kafka.)

Mamardashvili, M.K. (1986-7) 'Besedy o myshlenii' (Conversations about Thinking), lecture series delivered at Tbilisi University, in V.A. Kruglikov (ed.) *'Mysl' izrechennaia… ': sbornik nauchnykh statei*, Moscow, 1991, 13-50.(Meditations on the unexpected origins of a thought; on the difficulty of willing a desire versus willing an insight; the responsibilities that accrue to thinking.)

Mamardashvili, M.K. (1987) 'Filosofiia i svoboda' (Philosophy and Freedom) (lecture), in *Kak ya ponimayu filosofiiu (How I Understand Philosophy),* Moscow 1990, 365-74.(The Good as a productive state, not as an attribute or a product, because freedom can only produce more of itself; Russia as a land of 'eternal pregnancy'.)

Mamardashvili, M.K. (1990a) *Kak ya ponimayu filosofiiu (How I Understand Philosophy)* Moscow.(A collection of sixteen seminal lectures and interviews, and fifteen formal articles, from the 1970s to 1990s.)

Mamardachvili [Mamardashvili] (1990b) *'La pensée empêchée (Entretien avec Annie Epelboin)'*, Editions de l'Aube.(Biographical material.)

Mamardachvili [Mamardashvili] (1991) *Kartezianskie razmyshleniia (Cartesian Meditations)*, lectures delivered in Moscow, expanded and published in book form, Moscow, 1993.(On Descartes the man and his masks; the desirability of thinking in the present; thought and epiphany; the responsibilities of becoming conscious.)

'Pamiati filosofa' (In Commemoration of the Philosopher), special forum devoted to Mamardashvili in *Voprosy filosofii* (1991) 5: 3-25.(Memoiristic and eulogistic articles by seven scholar-disciples, including Iu. Senokosov, M. Ryklin, A. Piatigorskii and A. Akhutin.)

Mandeville, Bernard (1670-1733)

Bernard Mandeville's Fable of the Bees (1714) scandalized contemporaries by arguing that the flourishing commercial society they valued depended on vices they denounced. It resulted not only from the complementary satisfaction of appetites but was also based upon pride, envy and shame, which Mandeville traced to 'self-liking'. Numerous individuals, driven by their own desires, acted independently to produce goods which required extensive, cooperative operations - an idea central to the economic concept of a market.

Mandeville initially appeared to credit 'skilful politicians' with originating morality and society. However, in defending and expounding his views, he set out 'conjectural histories' of the gradual development of many complex social activities and institutions, including language and society itself, thereby denying that they had been invented by public spirited heroes. Throughout his works, Mandeville adopted a strict criterion of virtue, repeatedly denying that he was advocating, rather than exposing, the vices he identified as inherent in human society.

1 Early writings

Bernard Mandeville studied philosophy and medicine at Leiden, qualifying in 1691. In the mid-1690s he settled in England, specializing in nervous and digestive disorders. His early verse works included *Some Fables after the Easie and Familiar Method of Monsieur de la Fontaine* (1703; enlarged into *Aesop Dress'd*, 1704), two tales from which were by Mandeville himself. In 1705 he published a longer original verse fable, *The Grumbling Hive: or, Knaves Turn'd Honest*, whose bees continually complain of the vices and faults of their society, despite its power and prosperity. Granted virtue and honesty by Jove, they decline into contented, impoverished simplicity.

Mandeville then turned to female dialogues. In *The Virgin Unmask'd* (1709) 'an elderly maiden lady' advises her niece against the servility of marriage and lectures about the danger to Europe posed by Louis XIV. In the period 1709-10, Mandeville wrote thirty-two 'Lucinda' and 'Artesia' papers for the *Female Tatler*, an imitator of Richard Steele's *Tatler*. Mandeville ridiculed Steele's encomiums on the dignity of human nature and his advocacy of quasi-aristocratic 'politeness'; his 'Oxford gentleman' maintained that both sociability and prosperity were based on vice - on pride, flattery and the invention and satisfaction of luxurious desires. His 'sisters' debated honour, the advisability of military service in Marlborough's wars and the possibility of living to make money. Eight papers contended that women are fully capable of all the traditional male virtues, giving numerous historical, biblical and mythical examples (Goldsmith 1985).

2 Human nature and morality

The Fable of the Bees: or, Private Vices, Publick Benefits (1714), Mandeville's best-known work, reprinted *The Grumbling Hive*, adding extensive remarks and essays which analysed human conduct, finding it motivated by avarice, prodigality, envy, pride, honour, shame and luxury - with contrary passions balancing each other. 'Skilful politicians', moralists and lawgivers had socialized human beings by persuading them to restrain their immediate self-interested desires in return for the praise accorded to their noble self-sacrifice, thereby gratifying their desires to think well of themselves and be admired by others.

Much of this account of human nature was derived from the French *moralistes* and Pierre Bayle (see Bayle, P. §1; Mandeville 1714; Horne 1978; Hundert 1994), who had also pointed out the worldly benefits of unregenerate human conduct. Defining virtue as requiring self-denial for the good of others or one's own rational improvement enabled Mandeville to claim that he condemned the vicious passions to which he traced all human conduct, including apparently religious or virtuous conduct. Contemporary critics (for example, William Law and George Berkeley) accused Mandeville of advocating vice and subverting the standards of right conduct; Adam Smith, in his *Theory of Moral Sentiments* (1759, part VII, sect. ii, ch. 4), calls Mandeville's a 'licentious system' because it removes the distinction between vice and virtue. Kaye (Mandeville 1714) argued that Mandeville tended towards a consequentialist acceptance of the benefits of vice thereby implying a *reductio* of his professed strict (or 'rigourist') standard of virtue. None the less some commentators have accepted Mandeville's claim, reiterated in his last work *A Letter to Dion* (1732), that Dion's book *Alciphron* so misrepresented the *Fable of the Bees* that Berkeley could not have read that work (Monro 1975). Mandeville's satiric analysis of human nature along with

his scorn for reformers and standards of 'politeness' and virtue have puzzled subsequent commentators as well as his contemporaries (Castiglione 1986).

Originally aimed at Steele (in the *Female Tatler* papers and the first edition of the *Fable*) and at the proselytizing Societies for the Reformation of Manners, 'A Search into the Nature of Society', added to the second edition of the *Fable* (1723), extended the attack to the Third Earl of Shaftesbury. Also added to that edition was the 'Essay on Charity and Charity-Schools', which resulted in the *Fable*'s notoriety. In it Mandeville distinguished true charity from natural pity or compassion, discovered pride behind magnificent charitable bequests, asserted that charity schools were promoted by parish busybodies to confirm their sense of self-importance, and denied that the schools were socially beneficial in decreasing irreligion and crime, claiming rather that they were harmful in providing poor children with education and aspirations incompatible with the life of drudgery required of them by a prosperous commercial society. This provoked the *Fable*'s being presented as a public nuisance by a Middlesex Grand Jury and incited numerous refutations, most notably William Law and Francis Hutcheson (see Hutcheson, F. §§2-3).

It seems likely that a materialist and naturalist theory underlay Mandeville's ridicule of the dignity of human nature. The *Fable* treats humans as similar to other mammals in their anatomy, feelings, motives and behaviour - a rejection of the Cartesianism Mandeville learned at university. Its discussion of the slaughter and eating of higher animals and the debate between a lion and a man about superiority support that hypothesis, as do the methodological views expressed in Mandeville's *Treatise of the Hypocondriack and Hysterick Passions* (1711, 1730). This *Treatise* is a set of medical dialogues in which the doctor (clearly Mandeville) talks his patients into cures based on simpler diets, more exercise and fewer, milder medicines; he advocates the empirical study of diseases, sceptically rejecting fashionable and fanciful medical theories.

3 Economics

The paradox of private vices creating public benefits was illustrated by showing how natural and moral evils, such as disasters like the Great Fire of London, crimes like theft, vices like prostitution and harmful activities like the liquor trade, benefited society by providing work, circulating wealth, preserving chastity and, through taxes, by supporting the state. Thus Mandeville extended his 'selfish' conception of human nature, which has reminded commentators of Hobbes (see Hobbes, T. §6), into the thesis that human needs and vices produce social wellbeing. By serving the desires of others in order to satisfy their own desires, individuals acting independently produce complex social processes and institutions (including brewing, baking and, in 1723, the worldwide activity necessary to provide the luxury of scarlet coats for common soldiers). Hayek (1966) therefore credited Mandeville with the basic insight involved in the theory of the free market; namely, the social importance of the unintended consequences of individual actions. But claims that Mandeville was a conscious precursor of classical economics are exaggerated (Goldsmith 1985). Despite some passages advocating free trade, rejecting sumptuary laws, defending luxury, accepting the export of specie (gold and silver) and insisting that a nation must buy foreign goods if it expects to sell its goods abroad, Mandeville also states typically mercantilist views without expounding a clear economic theory (Horne 1978). Government must maintain a system of justice, provide defence and also regulate internal and external trade. Only *A Modest Defence of Public Stews* (1724), usually attributed (without definite proof) to Mandeville, provides a clear example of a self-regulating system of supply and demand - a scheme for a system of public houses of prostitution.

4 Later writings

In 1720, before the *Fable*'s notoriety, Mandeville published the moderate, whiggish *Free Thoughts on Religion*. Relying on Bayle to the point of plagiarism, Mandeville sceptically advocated irenic tolerance while expressing anticlerical views (also found in the *Fable*). *Free Thoughts* supported the Protestant succession, the Hanoverian dynasty and the British mixed constitution.

In two later works, signed 'by the author of the *Fable of the Bees*', Mandeville supplemented and defended his views. Both were dialogues between the same principal interlocutors: Cleomenes, who combines Christianity with advocacy of Mandeville's doctrines, and the worldly, sceptical Horatio. *The Fable of the Bees. Part II* (1729) explicitly distinguishes between two types of self-gratification: self-love (satisfying self-preservatory desires) and self-liking (satisfying the desires for superiority, admiration and one's good opinion of oneself). (Rousseau later

used the same distinction.) *An Enquiry into the Origin of Honour and the Usefulness of Christianity in War* (1732) not only pursues Mandeville's discussion of honour and contrasts true with nominal religion, but also further refines the analysis of self-liking in showing that it causes both shame and pride. The *Fable Part II* is especially notable for elaborating the historical thesis suggested in Mandeville's earlier remarks on the development of artefacts, processes and institutions (Goldsmith 1985). The designs of ships and clocks are the result of the labour and experience of many ages. So too are the elaborate laws and the complex institutions of government which - contrary to some previous views - have not been invented by heroic individual benefactors and lawgivers. The conjectural history of the stages of human development from animal existence through savagery to commercial society, already indicated as early as the *Female Tatler*, shows that the *Fable*'s story of the civilizing of humans by skilful politicians and moralists is not to be taken literally. In holding that the development of language itself must have taken many ages, Mandeville implicitly rejected literal, biblical chronology.

Mandeville's views were widely known and extensively used and commented on in the eighteenth century, by thinkers such as Hutcheson, Voltaire and Rousseau among others; David Hume and Adam Smith clearly knew Mandeville's discussion of human nature, the utility of vice and the beneficial results of complex social interaction (Goldsmith 1988; Hundert 1994).

M.M. GOLDSMITH

List of works

Mandeville, B. (1703) *Some Fables after the Easie and Familiar Method of Monsieur de la Fontaine*, London: Richard Wellington; enlarged edn, *Aesop Dress'd; or a Collection of Fables Writ in Familiar Verse*, London: Richard Wellington, 1704; reset edn of *Aesop Dress'd*, London: 'sold at Lock's-Head adjoyning to Ludgate', 1727[?]; reprint of reset edn of *Aesop Dress'd*, intro. J.S. Shea, Augustan Reprint Society Publication no. 120, Los Angeles, CA: Augustan Reprint Society, 1966.(Verse fables, based on La Fontaine's version of *Aesop*, but containing two original fables composed by Mandeville.)

Mandeville, B. (1705) *The Grumbling Hive: or, Knaves Turn'd Honest*, London: printed for S. Ballard and sold by A. Baldwin.(The verse fable used in *The Fable of the Bees*.)

Mandeville, B. (1709) *The Virgin Unmask'd: or, Female Dialogues Bewixt an Elderly Maiden Lady, and Her Niece*, London: sold by J. Morphew and J. Woodward; reprinted, intro. S.H. Good, Delmar, NY: Scholars' Facsimiles, 1975.(Dialogues on mores, manners and political affairs.)

Mandeville, B. (1709-10) *The Female Tatler*.(Thirty-two issues between numbers 52, 2 November 1709, and 111, 29 March 1710, signed 'Lucinda' and 'Artesia', discussing topics including the origin and development of society, honour and female virtue.)

Mandeville, B. (1711) *A Treatise of the Hypocondriack and Hysterick Passions*, London: printed for the author, D. Leach, W. Taylor and J. Woodward; enlarged 3rd edn, *A Treatise of the Hypocondriack and Hysterick Diseases*, London: printed for J. Tonson, 1730; reprinted 1st edn and reprinted 3rd edn, intro. S.H. Good, Delmar, NY: Scholars' Facsimiles, 1976.(Dialogues between doctor and patients on the causes and cures of nervous and digestive diseases.)

Mandeville, B. (1714) *The Fable of the Bees: or, Private Vices, Publick Benefits*, London: printed for J. Roberts; 2nd edn, enlarged, London: printed for E. Parker, 1723; 3rd edn, enlarged, London: printed for J. Roberts, 1724; reprinted, ed. F.B. Kaye, Oxford: Clarendon Press, 1924.(Mandeville's best-known work. Kaye's classic critical edition includes life, bibliography, annotations, discussions of Mandeville's thought, its background and influence, brief summaries of contemporary critics and a chronological list of references to Mandeville's work to 1923.)

Mandeville, B. (1729) *The Fable of the Bees. Part II*, London: printed for J. Roberts; reprinted, ed. F.B. Kaye, Oxford: Clarendon Press, 1924, vol. 2; reprinted, Indianapolis, IN: Liberty Classics, 1988.(Dialogues expanding, explaining and refining the *Fable*'s doctrines; included in Kaye's classic edition.)

Mandeville, B. (1720) *Free Thoughts on Religion, the Church, and National Happiness*, London: sold by T. Jauncy and J. Roberts; reprinted, intro. S.H. Good, Delmar, NY: Scholars' Facsimiles, 1981; 2nd edn, London: printed for John Brotherton, 1729; reprinted, Stuttgart-Bad Cannstatt: Frommann, 1969.(Discussion of religion heavily indebted to Pierre Bayle, otherwise relatively straightforward advocacy of toleration, anticlericalism and political whiggism.)

Mandeville, B. (1724) *A Modest Defence of Public Stews: or, An Essay upon Whoring, as it is now practis'd in these Kingdoms*, London: printed by A. Moore; reprinted, intro. R.I. Cook, Los Angeles, CA: Augustan Reprint Society, no. 162, 1973.(Standardly attributed to Mandeville; advocates public houses of prostitution to preserve

chastity.)

Mandeville, B. (1732) *An Enquiry into the Origin of Honour and the Usefulness of Christianity in War*, London: printed for J. Brotherton, 1732; reprinted, intro. M.M. Goldsmith, London: F. Cass, 1972.(Dialogues on honour and the distinction between real and nominal Christianity.)

Mandeville, B. (1732) *A Letter to Dion, Occasion'd by his Book call'd Alciphron, or the Minute Philosopher*, London: printed for J. Roberts; reprinted, intro. J. Viner, Los Angeles, CA: Augustan Reprint Society, no. 41, 1953.(Defends the *Fable of the Bees* on the grounds that it advocates strict morality and exposes vice; Viner denies that Mandeville advocated *laissez-faire* while favouring mercantilist government intervention.)

Manicheism

Manicheism is a defunct religion, born in Mesopotamia in the third century AD *and last attested in the sixteenth century in China. Its founder, Mani (*c.*216-76), had some familiarity with Judaism, Christianity, Zoroastrianism and Buddhism, and aimed to supplant them all. He taught a form of dualism, influenced by earlier Gnostics: God is opposed by forces of darkness; they, not God, created human beings, who nevertheless contain particles of light which can be released by abstemious living. Two points of contrast with Catholic Christianity are particularly striking. First, in Manicheism, sinfulness is the natural state of human beings (because of their creators), and does not stem from Adam's Fall. Second, the Manichean God did not create and does not control the forces of darkness (although he will eventually triumph); hence the problem of evil does not arise in as stark a form as it does for the all-powerful Christian God.*

Although Mani's own missionary journeys took him eastwards, it was in the Roman Empire to the west that the main impact of his teaching was first felt; Augustine of Hippo was an adherent for nine years. The religion was eventually suppressed in the Roman Empire, and driven east by the Arab conquest of Mesopotamia. In the West, various Christian heresies were loosely called Manichean throughout the Middle Ages.

1 The background

Dualism emerges into history with the Persian prophet Zoroaster (or Zarathustra), who lived perhaps as early as the thirteenth century BC, and who taught that the High God Zervan or his son Ormuzd (Mazda) battles with Ahriman, the Spirit of Darkness, and will one day send a Saviour to redeem mankind. Here we have the seeds of Mani's religion, seeds that may have been nourished by the Zoroastrian state cult of the Sassanian dynasty which came to power in Persia during Mani's lifetime. But a stronger affinity was with Gnosticism. Gnostic tenets, perhaps originating among certain 'God-fearing' Judaic communities (and perhaps themselves owing something to much more ancient Zoroastrian influence on Judaism), become known to us around the end of the first century AD. Many of the groups they affected, such as the followers of Marcion (d. *c.*160), absorbed enough Christianity to be attacked as Christian heretics.

Within much diversity the common features of Gnosticism were these. God the First Principle emanated divine associates or 'Aeons'. Among them was one who through pride or curiosity fell. It was this one, the Demiurge, who created the visible world and human beings in it. Human beings contain a spark of divinity, which it became God's purpose to rescue by imparting knowledge, gnosis, through his messenger Jesus. Gnostics repudiated the Old Testament, sometimes identifying the Demiurge with Yahweh and honouring Yahweh's opponents such as the Serpent and the Sodomites. Jesus was not born, or was born through Mary's ear, and he stood by the cross while a surrogate phantom suffered and died in his place. Gnosis is imparted only to the initiated. It teaches that the human body is evil, and it therefore enjoins ascetic practices and deplores procreation (see Gnosticism).

2 Mani

Mani (or Manes or Manichaeus) was born around 216 and brought up near Ctesiphon on the Tigris among a sect of baptists apparently founded a century earlier by a Jew named Elchasai. The sect observed the Sabbath, washed a great deal, and expected the imminent end of the world following the appearance of a final prophet. At the age of 12, and again at 24, Mani saw visions which he came to compare with the apostle Paul's. Like Paul he felt called to renounce the legalism of his upbringing and to take a message to the world; unlike Paul's, his message included a complete cosmological story. With the favour of the Sassanian king Shapur I he preached in Persia, organized missions as far west as Alexandria, and himself travelled eastwards, perhaps to India. After the death of Shapur's successor in 273 Mani fell out with the next king and was confined to prison, where he died in 276.

Mani held that God, the father of truth, exists before all things and persists after all things, and that everything exists through his power (*Concerning the Origin of His Body*, 66.4-15; Cameron and Dewey 1979: 52-3). But he also warned against those who 'teach that good and bad come from the same source, and introduce a single principle, not distinguishing or dividing darkness from light and good from bad…as we preach' ([Hegemonius] v). In prosaic summary, the story he preached was this. When first the Lord of Darkness and his demons invaded the realm of light, God sent Primeval Man attired in bright elements to resist them. But Primeval Man was defeated

and stripped of his attire, which the demons swallowed. In his quest to retrieve this stolen light God emanated seductive Messengers, the sight of whom caused emissions and abortions among the demons, from which sprang plants and beasts. Some of the light being thus trapped anew, a demon couple engendered Adam as a repository for most of the remainder. With Jesus' help we, as Adam's descendants, can by breathing and belching release our light upwards, feeding the moon as it waxes, which as it wanes feeds the sun in turn; but both eating and procreation have the contrary effect of trapping light. In the end Jesus will come again and light will triumph.

Mani's church was organized, with grand books, music, bishops and eventually monasteries, for the purpose of assisting God in this cosmic struggle. Its membership was divided between Elect and Hearers. Even Hearers (such as Augustine was) must not eat meat, or kill, must fast on Sundays, avoid procreation, and above all sustain the Elect - men and women - who were additionally forbidden to drink wine, copulate, farm, or prepare their own food.

The Manichees were interested in natural, especially celestial, phenomena and offered explanations of them which had to be consistent with Mani's cosmology.

3 Augustine and the Manichees

Perhaps in emulation of Paul, Mani signed his letters 'Apostle of Jesus Christ'. In Augustine's day the African Manichees claimed Christianity for their own and called Catholics *semichristiani*. One thing that underlay this surprising pretension was the Manichees' refusal to compromise the austerity they discerned in Paul's primitive Christian communities. Another may have been Mani's dualism, which not only could offer comfort to sensitive and frightened people in the thought that their sins and shortcomings stemmed from the machinations of superior powers, but could easily in the third and fourth centuries find heralds of that thought among Gnosticizing Christians. Manicheism is not strictly dualistic: its God is above all, and there is assurance that he will win in the end. Besides, Christians and Manichees shared a common cosmological concern with the problem of evil, agreeing both that it is a problem (why should there be any?) and that the solution lies in the past, when an originally happy state was upset by some fall from good behaviour.

What at this high level chiefly marks off Manicheism from Catholic Christianity, as the latter emerged in the councils and apologetics of the fourth century, is Mani's conception of human evils, sin and suffering, as tracing their origin back to an act - creation by demons - which unlike the biblical Fall was not the act of any human. Thus the two religions differ in their anthropology: for Manichees, sin and suffering are our natural state, not an Adam-induced lapse from it (see Sin §2). Augustine saw that difference, and used it to frame the risky charge that Manichean metaphysics leaves no room for human responsibility - risky because he was later to find the same charge brought against his own Catholic metaphysics by the Pelagians (see Augustine (§§6, 9, 12); Pelagianism §1-2). Manichees also, of course, seemed to have a readier means than Catholics of exculpating God from complicity in evil; for their God had not created and did not control the powers of darkness.

4 Dualism in Christianity

Augustine wrote of the time when Manicheism was losing its grip on him, 'It still seemed to me that it is not we who sin, but some other nature within us' (*Confessions*, 5.10.18); here was one comfort he would lose by resuming Catholic Christianity. Another was freedom to criticize the Bible, for the early Manichees won much of their missionary success by an aggressive policy of mocking the Old Testament and exposing inconsistencies in the Catholic canon of the New (their own New Testament canon was more Gnostic). But aggressiveness faded under persecution in the West, till the religion was exterminated from Christendom by about 600. It continued in Mesopotamia until driven east by the Arab conquest in the seventh century. For a time it was the state religion of the Uighur Turks in Sinkiang, and from the T'ang period it established a lasting presence in China, being last attested on the Fukien coast in the sixteenth century.

In Christendom, 'Manichee' became an opprobrious epithet for heresies that pronounced human nature evil (so excluding redemption) and harboured a class of Elect (so rejecting infant baptism). Paulicians, who flourished in Armenia and the eastern confines of the Roman Empire in the eighth and ninth centuries, believed that the Demiurge, not God, made the world and Jesus only seemed to die. In tenth-century Bulgaria, Bogomil (Theophilus, 'God-beloved') echoed much of Mani's cosmology and ethics. His views guided the

thirteenth-century Sclavonian church of Bosnia, called Patarene by the West. During the twelfth century there were Poblicans in Flanders, perhaps inheritors of Paulicianism through itinerant weavers. And the Cathars of the same period, powerful in southern France until de Montfort's 'crusade' overthrew them, joined Manichean dietary and sexual proscriptions with the old Gnostic rejection of Christ's humanity. All of these sects, while attracting support from simple people, had leaders who knew history and tried to model their lives on past practice: not indeed on the outlandish Mani, about whom they probably knew little and cared less, but on primitive Christianity as transmitted through early Gnosticism. They succumbed to Catholic persecution in the West, and many in the Balkans converted to Islam after the Turkish conquests of the fifteenth century. But even in modern times like-minded movements arise now and again, nourished by certain books of the Bible, especially Daniel and Revelation.

References and further reading

Mani is credited with seven works in Syriac, and one in Middle Persian addressed to King Shapur, but only fragments survive. Traditions were preserved by Muhammad ben Ishâk's 'Doctrines of the Manicheans' in the *Fihrist*, a history of Arabic literature to 987 compiled by an-Nadîm, and less reliably in various hostile writings from the fourth and fifth centuries by Christians and others. Further Manichean writings have come to light during the twentieth century in Chinese and other languages (Turfan 1904-15, Tun-huang 1905), Coptic (Egypt, Medinet Madi 1930), Greek (Cologne 1969) and Latin. The greater part of the Coptic collection, including letters of Mani himself, went to the Berlin Academy from where it disappeared in 1945 before publication was complete; most of the remainder, including homilies edited by Polotsky and a Psalm Book edited by Allberry, is in the Chester Beatty Collection in Dublin. Many of these texts are collected in Adam (1969). The Cologne manuscript edited by Koenen and Römer is a gospel-cum-apocalypse in Greek from a Syriac original, some of it presented as autobiography by Mani. It dates from about 400.

Manifoldness, Jaina theory of

The Sanskrit term anekāntavāda *literally means 'not-one-sided doctrine', and refers to the Jaina epistemological theory of manifold standpoints from which an object may be considered and the manifold predications that can be made with regard to it. It evolved out of Mahāvīra's ethical emphasis on nonviolence - the multidimensional nature of objects should not be violated by single, absolutist (*ekānta*) predications about them. Respect for life is thus transformed in its philosophical application into a principle of respect for other views. The theory has come to be called the central philosophy of Jainism and was developed in a milieu of intensive debate between the various Indian philosophical schools. Though the theory was based on Mahāvīra's teaching, it implicitly presupposed, in its later highly developed form, various philosophical alternatives (representing the views of other schools of thought), which it sought to syncretize. Each standpoint and predication presents a partial truth and, according to Jainism, only the theory of manifoldness does justice to the complex nature of entities. While it can be seen as an attempt to practice intellectual nonviolence, it is evident that the Jainas adhered to it zealously and defended it as vehemently as the others did their own views.*

1 Historical background

There is an obvious similarity between the Jaina theory of manifold predication (*anekāntavāda*) and its precursor, the theory of analysis or differentiation (*vibhajyavāda*), which is more famous as Buddha's method of dealing with questions, but was also employed by Mahāvīra. Buddha is renowned for not categorically answering metaphysical questions and for seeking an appropriate answer by breaking up (*vibhajya*) a question into its component parts, often thereby demonstrating it to be a pseudo-question. B.K. Matilal (1981: 11) refers to two types of this theory: the first 'operates by dividing the subject class into sub-classes' (to the question 'Will all beings be reborn?' the answer is 'Only those with defilements'); the second 'operates by specifying or relativizing the predicate' (the answer to the question 'Is man superior or inferior?' is 'Man is inferior to gods and superior to the lower beings'). According to Matilal, it was the second type that Mahāvīra adopted and which was developed into the *anekānta* method.

The *BhagavatīSūtra*, part of the Jaina canon, has examples of this style of teaching that are comparable with the better-known ones of Buddha (for example, IX, 33, 485b; Deleu: 164). To quote Matilal again:

> The Buddha's method was one of withdrawal from philosophical disputes, for he avoided committing himself to any extreme view. But Mahāvīra's method was one of commitment, for he attempted to understand the points of view of the fighting parties (in a philosophical dispute) so that their dispute could be resolved and reconciled. Thus, the essence of the *anekānta*-*vāda* lies in exposing and making explicit the standpoints or presuppositions of the different philosophical schools.
>
> (1981: 23)

Both Jaina and Buddhist sources refer to one Gośāla, a contemporary of Mahāvīra and Buddha and founder of the Ājīvaka sect, which disappeared very soon after his death. He is reputed to have asserted that all entities have a triple character: existent, nonexistent, and both existent and nonexistent (or living, nonliving, and both living and nonliving). The Jaina theory seems to interpret these as positive, negative, and both positive and negative; when they were combined with the possibility that an entity can have an inexpressible nature, a sevenfold formula emerged (see §3).

Just as the Buddhists used the famous fourfold alternative to establish the doctrine of the void (Nāgārjuna's alternatives are: everything is true; not everything is true; both everything is true, and not everything is true; or neither everything is true nor is everything not true), so the Jaina developed the theory of standpoints and sevenfold predication to defend the doctrine of manifoldness (see Nāgārjuna §3). The key to the Jaina position is the need to qualify an assertion or to make it conditionally true in order to leave open other possibilities. This represents the Jaina respect for the views of other schools and at the same time implicitly criticizes their absolutist stands, which have the potential for dogmatism and intolerance. The way to overcome one-sided doctrines is to adopt Mahāvīra's method of accepting metaphysical theories with a qualified affirmation. The philosophic attempt to come as close as possible to capturing the true, multidimensional nature of an entity is to qualify one's assertion with the particle *syāt*.

2 The significance of *syāt*

The Jaina theory of the manifoldness of reality has two aspects: the doctrine of standpoints (*nayavāda*) and the sevenfold predication (*saptabhaōgī*) associated with it, whereby each type of predication is an epistemological assertion from a certain viewpoint (*syāt*). The theory of manifoldness (*anekāntavāda*) is often used as a synonym for the theory of viewpoints (*syādvāda*). The word *syāt* is identical with a verbal form (the third person singular of the optative mood) of the Sanskrit root 'to be' (*as*), and means things like 'perhaps, possibly, maybe it is or exists'. This has led to a description of the theory as agnostic, giving the impression of doubt, uncertainty and indeterminacy and an inability definitely to determine an object of investigation. The crucial point of the theory is missed, however, if the word is interpreted as a verbal form. Each of the seven statements (see §3) which may be explicitly made with respect to an entity has, in addition to the word *syāt*, a finite form of the same root 'to be', the third person singular present indicative (*asti*, implicit in the fourth case). The technical sense in which it is employed by the Jainas, which semantically does justice to its use, requires an analysis of *syāt* as an indeclinable word meaning 'from a point of view' or 'in a certain sense', with the obvious extension 'from another point of view' or 'in another sense'. Thus, the Jaina theory does not imply that it is epistemologically difficult to determine the nature of an object, but rather that it can be definitely determined from several particular points of view, even though some assertions have a negative structure or express indescribability.

3 The seven standpoints

The two aspects of the theory of manifoldness mentioned at the beginning of §2 relate to two different but theoretically related contexts in which it is employed. The doctrine of standpoints (*nayavāda*) is the general framework indicating seven ways of considering an object or entity, and the theory of viewpoints (*syādvāda*) represents the seven assertions which may be made regarding an object or entity. Both aspects are intended to demonstrate how partial truths about entities are presented. Jainism makes a clear distinction between knowledge of an entity as a whole and knowledge of a part or an aspect of an entity. This is the epistemological distinction implicit in the terms *pramāṇa*, which signifies complete knowledge of an entity in all its qualities and modes of appearance, and *naya*, which signifies partial knowledge with reference to an entity as it appears to be in the present time and place, having a particular quality and mode which may later change. Complete knowledge of an entity, simultaneously grasping it in all its modes and in all possible ways, occurs only in the case of beings unhindered by karma and is a sign of omniscience. In the case of human knowledge, which is restricted to the functions of the sense organs whose capacities are impeded by karma, only partial knowledge is posssible. The doctrine of standpoints thus represents the various kinds of partial knowledge accessible to human beings. It serves two functions: it facilitates analyses of objects of inquiry and, when applied to other schools of thought, it enables Jainism to classify the partial truths of those schools in terms of one or the other standpoint.

Jainism evinces what may be called a passion for enumeration, classification and categorization of practically all the major philosophical terms: the single term 'karma', for instance, is divided into eight important kinds with a further 148 others; and knowledge is deemed to be derived in two ways, each with its own specific kinds (see Jaina philosophy §2). Theoretically, an infinite number of standpoints are possible when considering an entity, but traditionally Jainism enumerates the following seven in the context of the theory of manifoldness:

(1) The common or nondistinguished standpoint (*naigamanaya*) refers to an entity without taking its general and specific characteristics or qualities into consideration. The words 'jar' and 'cloth', for example, can be used in two senses according to this standpoint. They may refer to specific objects within one's view or they may refer to the class of objects that they denote. The example of 'cooking' is also mentioned here; ambiguity can arise when no clear distinction is made between the activity of actually cooking and the preliminary preparations. The general and particular properties of an object or activity are not explicitly distinguished in this standpoint, yet statements concerning 'jar' and 'cooking' are easily understandable. This standpoint represents what is understood conventionally; it is emphasized, according to the Jainas, by the Nyāya-Vaiśeṣika school. The fifth-century Jaina philosopher Siddhasena Divākara does not recognize this as a separate standpoint.

(2) The general or collective standpoint (*saōgrahanaya*) takes into consideration the class to which an entity belongs, as, for example, when one refers to fruit trees in general. This point is indirectly related to the problem of universals and treats class properties as but one way among others of referring to entities. Class properties like

'fruitness' and 'treeness' are treated as representing a partial truth about an entity. With reference to the all-encompassing category 'being', this standpoint represents the Vedānta school, with its notion of Brahman as the only ultimately real substance. Whereas the first standpoint may be ambiguous in that it can refer to both a particular object as well as a class of objects, this standpoint represents the partial knowledge of an entity because it emphasizes the general aspect alone.

(3) The practical standpoint (*vyavahāranaya*) is a complement to the second and a corollary to the first in that it refers to something specific. When one asks for a fruit, the reference is to something specific, for fruit in general cannot be brought. It is a standpoint which implicitly particularizes an entity and, like the first standpoint, is generally understood. The practical standpoint implies classification and differentiation and is said to represent the view of the materialist Cārvāka school. Like the second standpoint, it avoids the ambiguity of the first, but is no less a partial standpoint, an emphasis on which can furnish only partial knowledge of an entity, because it emphasizes a single, particular object.

(4) The 'straight thread' standpoint (*ṛjusūtranaya*) considers an entity as it appears at the present moment, ignoring both its previous form and the one it will have in future. An emphasis on this partial truth leads to the metaphysical conclusion of existence as momentary. The Jaina theory includes the Buddhist doctrine of universal flux here as an example of the kind of partial truth furnished by this standpoint (see Momentariness, Buddhist doctrine of §1).

(5) The verbal standpoint (*śabdanaya*) represents the method of referring to an entity in terms of the syntactic relations between the words used in a sentence where the meaning is determined by grammatical inflections which can offer different semantic interpretations. The analysis of this standpoint is inextricably related to Sanskrit grammar. The meaning of a sentence is dependent on the relations between its words and these relations are grammatically governed. The partial knowledge is represented by the specific interpretation given to the relations, which then furnish a meaning relative to it.

(6) The subtle standpoint (*samabhirūḍhanaya*) makes a subtle distinction between synonyms in terms of their etymology. This standpoint represents a partial truth in which only etymological differences are emphasized, whereas the object referred to is the same. Thus the same person may be referred to as a king, regent, or sovereign; the Sanskrit equivalents of these words can produce different meanings depending on their derivations. A partial view is represented according to this standpoint when the meaning of synonymous words is explained *only* on the basis of their etymology.

(7) The 'thus-happened' standpoint (*evambhūtanaya*) is an extension of the above in that it restricts the meaning of a word to a particular occasion of use. Thus the word 'cook' should be used, according to this standpoint, only when a person is actually cooking. The restriction of the use of words to actual cases gives only a partial truth because it either ignores a person's other activities, or could imply that a person is not a cook by occupation (say) when doing something else.

The second aspect of the Jaina theory of manifoldness, which is correlated with the theory of standpoints, represents statements or predications about an object that can be made from only one specific point of view. As with the seven standpoints, the seven viewpoints - which constitute the framework of the Jaina theory of sevenfold predication - are intended to apply to any specific entity. One can make the following assertions about any entity:

(i) From one point of view it exists (*syād asti*).
(ii) From one point of view it does not exist (*syān nāsti*).
(iii) From one point of view it exists and from another point of view it does not exist (*syād asti syān nāsti*). This assertion, combining (i) and (ii) into a single unit, does not apply simultaneously, thereby avoiding an apparent contradiction. The assertion may be fully expressed as, for example: 'from one point of view a pot exists (as a pot) and from another point of view it does not exist (as a tree).'
(iv) From one point of view it is inexpressible (*syād avaktavyam*).
(v) From one point of view it both exists and is inexpressible (*syād asti cāvaktavyam*).
(vi) From one point of view it both does not exist and is inexpressible (*syān nāsti cāvaktavyam*).
(vii) From one point of view it exists, does not exist and is also inexpressible (*syād asti ca nāsti cāvaktavyam*).

Jainism ascribes validity to the need for these kinds of assertions about an entity on the basis of lists of factors mentioned in the Jaina canon which were employed when investigating the nature of an entity. The lists originally

served as tools for investigating words, especially the titles and chapter titles of canonical texts, but later took on an epistemological significance when applied to assertions about entities in general. They were ‘gateways of investigation’ (*anuyogadvāra*) which served to ‘set down’ or ‘bring forward’ (*nikṣepa*) the context in which the investigation of an object applies. Of the several lists (containing up to thirteen items) that feature in the canonical texts, the list of four is the most popular. According to this list, clarity about an entity can be achieved if there is an analysis that considers it in terms of: the name or the word used to designate the entity; the form or the way in which it can be illustrated; the substance out of which it is constituted; and its specific state or condition at the moment of investigation. Other factors, such as place, time and the means by which an object is known, were also used, with analyses taking on complex dimensions when repetitively (and often futilely) applied to the objects with which an entity is compared. However, this method of analysis directly influenced the later form of the theory of manifoldness and served, in the last resort, as its justification. The historical background and traditional application of the theory were generally ignored by its critics when assessing its contribution.

The Jaina theory of manifoldness was regarded by the other schools of Indian philosophy as generally representing the entire Jaina philosophy, so much so that it was what they attacked above all. It was asserted that the theory is self-contradictory, and that it demonstrates an uncertain and vague standpoint, with equivocality as its greatest error. Jainism was criticized for not being in a position clearly to describe reality. This explains why the majority of Jaina thinkers take every opportunity to justify the theory (which thus features in practically all Jaina philosophical studies) and to vindicate the nonabsolutism of Jainism. One of the most insightful and even independent thinkers within Jainism is Vidyānandin (ninth century), who belonged to the Digambara tradition of Jainism. Accepting three basic kinds of predicates, the positive, the negative, and the neutralized or indescribable, he concludes that only seven combinations are possible, which shows that the Jaina theory of manifoldness takes all cases into consideration when analysing an entity.

Many-valued logics

Many-valued logics may be distinguished from classical logic on purely semantic grounds. One of the simplifying assumptions on which classical logic is based is the thesis of bivalence, which states that there are only two truth-values - true and false - and every sentence must be one or the other. Many-valued logics reject the thesis of bivalence and permit more than two truth-values.

1 Motivations

Bivalence, in conjunction with some plausible assumptions about the nature of time, seems to lead to determinism. It seems plausible that no matter what I do now, I cannot change what was the case yesterday. This fact suggests that statements about the past are not contingent in the way most of us feel that statements about the future are. Suppose we want to know whether Charles will go sailing tomorrow, Saturday. We think Charles is a free agent, and his going sailing tomorrow is dependent on how he feels, his view of the weather, and other such factors. Consider the sentence ‘Yesterday it was the case that Charles will go sailing on Saturday’. Since yesterday is past, the truth-value of this sentence is fixed, even if we do not now know what it is. If the sentence is true, then it must be the case that Charles is going to go sailing tomorrow; and if the sentence is false, then it must be the case that Charles is not going to go sailing tomorrow. Either way, it seems that whether or not Charles is going sailing tomorrow is already determined, so the notion of future contingency is an illusion.

One way of escaping this argument for determinism is to reject the thesis of bivalence. The most obvious first approach would be to insist on three truth-values: ‘true’, ‘false’ and ‘indeterminate’. This problem was discussed by Aristotle (in *De Interpretatione*), although his position on the issue of bivalence remains a matter of debate. Indeterminists, such as the Epicureans, rejected the thesis of bivalence; determinists, such as the Stoics, advocated it. In the modern era, the Polish logician Łukasiewicz developed several many-valued logics as a means to escape the determinist argument (see Łukasiewicz, J. §3).

Many other motivations for many-valued logics have been advanced. In every case, there is much debate over the extent to which many-valued logic solves the problems which motivated its advocacy.

Another ancient motivation for expanding the stock of truth-values was the consideration of modalities. Some sentences, for example, ‘Two plus two is four’, seem to be not just true, but *necessarily* true. ‘The sun is shining today’, however, may well be true, but is not necessarily true since we can imagine an alternative. Such considerations suggest having at least four truth-values: ‘necessarily true’, ‘contingently true’, ‘contingently false’, ‘necessarily false’. However, it has been shown that most important systems of modal logic do not correspond to any finite-valued semantics.

Another common motivation for many-valued logics is the consideration of uncertainty. Uncertainty from many sources has been considered: from the incompleteness of human knowledge; from the lack of termination of machine computations; from the conflicting judgment of expert opinion; from true statistical fluctuations in nature; and from accumulating error. A major problem is that uncertainties do not combine in a truth-functional way, but many-valued logics are generally truth-functional.

Many attributions which we commonly make every day (for example, ‘Charles is ugly’) seem to be vague, that is, subject to degree, rather than being black or white (see Vagueness). Investigations of many-valued logics have been motivated by attempts to deal with inherently vague aspects of natural language. Considerations of vagueness have led to interest in so-called ‘fuzzy logic’ in computing science and electrical engineering (see Fuzzy logic).

Many-valued logics have been advocated as a means of avoiding various paradoxes, including the usual semantic paradoxes (see Semantic paradoxes and theories of truth), such as the liar paradox, as well as paradoxes associated with the comprehension axiom of set theory (see Paradoxes of set and property). For the semantic paradoxes, unless the syntax of the language is unnaturally restricted so that crucial aspects of the semantics cannot even be expressed, versions of the paradoxes simply reappear. For example, suppose we have three truth-values, and consider the sentence ‘This sentence is either false or has indeterminate truth-value’. If its value is false, then what it says is true; if its value is indeterminate then what it says is true; but if its value is true, then it is either false or indeterminate. Similarly, the paradoxes of adopting the unrestricted comprehension axiom in axiomatic set theory

cannot be avoided solely by adopting a many-valued logic.

2 An example

As a simple example, suppose that instead of the classical semantic range of just ‘true’ and ‘false’, we use the following.

T: logically true
t: empirically true
U: undeterminable
f: empirically false
F: logically false

The values T and t are said to be ‘designated’ values, or ways of being true. The other values are said to be ‘undesignated’. We could give semantic characterizations for a great number of connectives, but here are just a few examples.

A	$J_{\mathrm{T}}(A)$	$J_{\mathrm{t}}(A)$	$J_{\mathrm{U}}(A)$	$J_{\mathrm{f}}(A)$	$J_{\mathrm{F}}(A)$	$\sim A$	$\neg A$
T	T	F	F	F	F	F	F
t	F	T	F	F	F	f	F
U	F	F	T	F	F	U	T
f	F	F	F	T	F	t	T
F	F	F	F	F	T	T	T

$\supset$	T	t	U	f	F
T	T	t	U	f	F
t	t	t	U	f	f
U	U	U	U	U	U
f	U	U	U	U	U
F	U	U	U	U	U

<>< *eq* >

$\rightarrow$	T	t	U	f	F
T	T	t	f	f	F
t	T	t	t	f	f
U	T	t	t	t	t
f	T	t	t	t	t
F	T	T	T	T	T

The J_i connectives have the property that $J_i(A)$ has the value T if and only if *A* has the value *i*. They are known as ‘autodescriptive’ operators; they allow the expression in the syntax of the underlying semantic motivation. While $\neg$ corresponds to ‘is not designated’, the connective $\sim$ is the more usual complement negation. The conditional $\supset$ reflects the view that if the antecedent is not true, then we cannot tell the value of the conditional. However, $\rightarrow$ parallels the usual material conditional. The disjunction operator $\vee$ is the usual ‘max’.

The connectives $\neg$, $\rightarrow$ and $\vee$ are ‘pseudo-classical’ operators; if we map all the designated values to ‘true’ and the undesignated values to ‘false’, then the truth-conditions for these operators correspond to the classical connectives. The connectives $\sim$ and $\supset$ are not pseudo-classical.

Given our semantic account, we may inquire about an appropriate proof theory. Note that if we restrict our language to $\sim$ and $\supset$, then there will be no logical truths (formulas that are always designated); any formula composed with just these two connectives will take the undesignated value U when all atomic formulas take value U. Hence a proof theory for tautologies would not be appropriate were our language so restricted. However, an axiomatization of the consequence relation would still be of interest, and would include such sequents as $A, A \supset B \vdash B$.

Although often presented as restrictions of classical systems, many-valued logics can almost always be formulated as conservative extensions of classical logic. The trick is to include pseudo-classical connectives in the language.

A classical proof theory may be stated using the pseudo-classical connectives. Then using the autodescriptive operators, the additional required principles can be formulated. For example, some principles arise simply by stating the truth-conditions for each connective. The last entry on the table for $\supset$, above, corresponds to $J_{\mathrm{F}}(A) \rightarrow (J_{\mathrm{F}}(B) \rightarrow J_{\mathrm{U}}(A \supset B))$ for an axiomatic system or to $J_{\mathrm{F}}(A), J_{\mathrm{F}}(B) \vdash J_{\mathrm{U}}(A \supset B)$ for a sequent system.

3 Technical matters

All the metatheoretical concerns raised with classical logic also arise with respect to many-valued logics. The model theory of many-valued logics can be developed in much the same way as that of classical logic. Depending on the specifics of the syntax, proof theories are formulated in all the usual varieties: axiomatic, natural deduction, single- and multiple-conclusion consequence relations. Many-valued extensions of non-classical logics may be constructed, and many-valued versions of standard identity theory have been formulated.

Two frequently encountered questions warrant special mention, though we provide only partial answers here. (1) Given an arbitrary semantic theory, can we always find a corresponding proof theory? For the finite-valued case, the answer is affirmative, providing the syntax has appropriate connectives; but if the syntax is limited, it may be impossible to formulate an appropriate proof theory for a single-conclusion consequence relation. For the infinite-valued case, most interesting quantificational systems will not be axiomatizable; even for propositional logics it will be impossible to formulate a finitistic proof theory if the syntax is rich enough (for example, including autodescriptive operators). (2) Given a proof theory, can we always find a corresponding many-valued semantics? If we are concerned only with logical truth (not consequence in general) and if the proof theory admits a rule of substitution, then there will always be an infinite-valued semantics, though the designated values may turn out not to be decidable.

Many-valued logics, philosophical issues in

The first philosophically-motivated use of many-valued truth tables arose with Jan Łukasiewicz in the 1920s. What exercised Łukasiewicz was a worry that the principle of bivalence, 'every statement is either true or false', involves an undesirable commitment to fatalism. Should not statements about the future whose eventual truth or falsity depends on the actions of free agents be given some third status - 'indeterminate', say - as opposed to being (now) regarded as determinately true or determinately false? To implement this idea in the context of the language of sentential logic (with conjunction, disjunction, implication and negation), we need to show - if the usual style of treatment of such connectives in a bivalent setting is to be followed - how the status of a compound formula is determined by the status of its components.

Łukasiewicz's decision as to how the appropriate three-valued truth-functions should look is recorded in truth tables in which (determinate) truth and falsity are represented by '1' and '3' respectively, with '2' for indeterminacy (see tables in the main body of the entry). Consider the formula $A \vee B$ *('A or B'), for example, when A has the value 2 and B has the value 1. The value of* $A \vee B$ *is 1, reasonably enough, since if A's eventual truth or falsity depends on how people freely act, but B is determinately true already, then* $A \vee B$ *is already true independently of such free action. There are no constraints as to which values may be assigned to propositional variables. The law of excluded middle is invalidated in the case of indeterminacy: if p is assigned the value 2, then* $p \vee \neg p$ *also has the value 2. This reflects Łukasiewicz's idea that such disjunctions as 'Either I shall die in a plane crash on January 1, 2030 or I shall not die in a plane crash on January 1, 2030' should not be counted as logical truths, on pain of incurring the fatalistic commitments already alluded to.*

Together with the choice of designated elements (which play the role in determining validity played by truth in the bivalent setting), Łukasiewicz's tables constitute a (logical) matrix. An alternative three-element matrix, the 1-Kleene matrix, involves putting $2 \rightarrow 2 = 2$*, leaving everything else unchanged. And a third such matrix, the 1,2-Kleene matrix, differs from this in taking as designated the set of values* $\{1, 2\}$ *rather than* $\{1\}$*. The 1-Kleene matrix has been proposed for the semantics of vagueness. In the case of a sentence applying a vague predicate, such as 'young', to an individual, the idea is that if the individual is a borderline case of the predicate (not definitely young, and not definitely not young, to use our example) then the value 2 is appropriate, while 1 and 3 are reserved for definite truths and falsehoods, respectively. Łukasiewicz also explored, as a technical curiosity, n-valued tables constructed on the same model, for higher values of n, as well as certain infinitely many-valued tables. Variations on this theme have included acknowledging as many values as there are real numbers, with similar applications to vagueness and approximation in mind.*

1 Second thoughts on some popular applications

Motivated by a concern that the principle of bivalence ('every statement is either true or false') involves an undesirable commitment to fatalism, Łukasiewicz introduced truth tables involving the value 'indeterminate' in addition to 'true' and 'false' in the 1920s (see Łukasiewicz 1970). His decision as to how these three truth-values should be combined is shown in the following tables:

$\wedge$	1	2	3
*1	1	2	3
2	2	2	3
3	3	3	3

$\vee$	1	2	3
1	1	1	1
2	1	2	2
3	1	2	3

$\rightarrow$	1	2	3
1	1	2	3
2	1	1	2
3	1	1	1

A	$\neg A$
1	3
2	2
3	1

The asterisk flagging the first occurrence of '1' in the tables is the conventional way of indicating that this value is 'designated': in other words, that this value plays the role, in defining validity, played by truth in the bivalent setting.

The formal apparatus introduced by these tables is a special case of the notion of a matrix *M* with which are associated an algebra (a non-empty set - here, the set of matrix elements - closed under some specified operations), that we may call $A(M)$; and a set of matrix elements which are to count as the designated elements, which we will call $D(M)$. An alternative three-element matrix, the 1-Kleene matrix, differs from Łukasiewicz's only in having $2 \rightarrow 2 = 2$. A third such matrix, the 1,2-Kleene matrix, differs from this in taking as designated the set of values $\{1, 2\}$ rather than $\{1\}$.

One might expect the term 'matrix' to apply to the individual tables for the connectives depicted in such diagrams, but the standard logical usage, reflected in the definition just given, means that it is the whole set of tables that depicts a single matrix. If we call this matrix *M*, then the set of *M*-elements is $\{1, 2, 3\}$ and the algebra $A(M)$ has operations '$\wedge$', '$\vee$', '$\rightarrow$', '$\neg$', behaving as depicted in the tables. (When more care is called for, we distinguish these operations from the connectives, writing something like '$\wedge^M$', '$\vee^M$' and so on.) Finally, $D(M) = \{1\}$. A logic which is - to use terminology defined in §2 below - 'determined by' a matrix with *n* elements but by no matrix with fewer than *n* elements is called an *n*-valued logic.

From the table for '$\vee$' we can see that $1 \vee 2 = 1$. While this seems satisfactory (if *A* is true then $A \vee B$ will be true regardless of the value assigned to *B*), we can see that all is not well by looking at another case. The table for '$\wedge$' tells us that $2 \wedge 2 = 2$: a result which is suggested by the case in which the two conjuncts concerned are independent ('I shall die in a plane crash', 'Britain will become a republic'), as well as by the case in which the conjuncts are identical, but which goes obviously wrong otherwise ('I shall die in a plane crash', 'I shall not die in a plane crash' - to take an extreme case). The falsity of the conjunction 'I shall die in a plane crash and I shall not die in a plane crash' is fixed regardless of how anyone decides to act. Thus it should receive the value 3. But of course we cannot simply emend Łukasiewicz's matrix and insert a '3' in the middle box of the '$\wedge$' table, since we shall then have the wrong result for the other cases. Similar reasoning applies in the case of disjunction: the disjunction of 'I shall die in a plane crash' and its negation is not something whose eventual truth can be prevented, so it should have the value 1. So we cannot acquiesce in Łukasiewicz's $2 \vee 2 = 2$. The only conclusion possible is that treating the threefold classification Łukasiewicz had in mind as a range of values with respect to which the familiarly truth-functional connectives could indeed be taken as truth-functional is misconceived. Not every threefold classification of statements gives us a three-valued logic.

It seems appropriate to return a similarly negative verdict on the proposed application of 3- (and more) element matrices, including the 1-Kleene matrix (see Cleave 1974), to vagueness (see Vagueness §3). In these and other cases the truth-functional paradigm is simply inappropriate for the notions being modelled (Geach 1949). The problem of failed truth-functionality which afflicts these approaches arises out of the fact that there is a linear ordering of the truth-values with respect to which '$\wedge$' and '$\vee$' are interpreted as *min* and *max*. In the case of Łukasiewicz's three-valued tables - contrary to what is suggested by the labelling - we are taking 1 as the greatest and 3 as the least, with 2 intermediate. Not all many-valued tables exhibit this kind of linear ordering, however, including some that Łukasiewicz himself proposed for treating modal notions; typically, though, there are more suggestive ways of developing the semantics for such applications than by the laying down of such tables (see Prior 1955). We return in §4 to other applications; we shall also have occasion to observe that the above talk of rejecting the principle of bivalence turns out on reflection to be somewhat dubious - even apropos of certain more promising applications of matrix semantics than those touched on above.

2 Logic

Suppose we have a matrix *M* and a formal language whose primitive connectives are in one-to-one correspondence with the operations of $A(M)$. Then an assignment of elements of *M* to the formulas of that language, in which $A(M)$ is used to compute the value of compounds on the basis of their components, will be called an *M*-evaluation. This generalizes the idea of a 'valuation', which term we shall always reserve for the bivalent case (so a valuation assigns either T or F to every formula), and we wish now to adapt the familiar idea of validity as preservation of truth. The resulting notion is to apply to sequents, and we begin by distinguishing three conceptions of what a sequent is to look like - three (as we shall say) 'logical frameworks'.

The most general framework we call SET-SET, and it takes a sequent of a given language to be something of the form $\Gamma \succ \Delta$ (read 'Γ, therefore Δ' or 'Γ yields Δ'), where Γ and Δ are arbitrary sets of formulas of that language (Blamey 1986). If we impose the condition that Δ has to be $\{B\}$ for some formula *B*, we have the more

restricted logical framework SET-FMLA, and write $\Gamma \succ B$ rather than $\Gamma \succ \{B\}$. Finally, if we impose, in addition to this condition on Δ, the further condition that Γ must be empty, we have the framework we call FMLA, and when no confusion arises we identify the sequents $\succ B$ (that is, $\emptyset \succ B$) which this framework provides with the formulas *B* themselves.

Early approaches to logic (Frege, Hilbert) used the framework FMLA, syntactically codifying a logic with the axiomatic method. The provable formulas were formal analogues of the 'logical truths' of that area of natural language being formalized. The sequents of SET-FMLA are formal analogues of arguments with premises on the left of the '$\succ$', and the conclusion to the right. For SET-SET, we have a generalization in which, roughly speaking, we may say that sets of formulas on the right are understood disjunctively, just as those on the left are (as in SET-FMLA) understood conjunctively. More precisely, in the bivalent setting, we say that a sequent $\Gamma \succ \Delta$ of SET-SET holds on a valuation *v* (for the language in question) just in case if $v(A) = \mathrm{T}$ for every $A \in \Gamma$, then $v(B) = \mathrm{T}$ for some $B \in \Delta$. Since the other logical frameworks simply restrict the class of sequents, we may use this same definition in connection with them. A set of sequents which contains all substitution instances of any of its elements will be what we have in mind as a *logic* in that framework. The set of sequents determined by a class of valuations is the set comprising precisely those sequents holding on each valuation in the class. This set may or may not constitute a logic, on the definition just given, depending on what class of valuations is chosen.

It remains to provide a 'matrix semantics' version of the above. We simply make clear the intention that the designated values are those which play the role of truth. Suppose, then, that *h* is an *M*-evaluation, for some matrix *M*; we say that the sequent $\Gamma \succ \Delta$ holds on *h* just in case

If $h(\Gamma) \subseteq D(M)$ then $h(\Delta) \cap D(M) \neq \emptyset$,

where $h(\Gamma)$ denotes $\{h(A) |\ A \in \Gamma\}$. Again, this definition fixes what it is for a sequent of SET-FMLA or FMLA to hold on an evaluation. Finally, a sequent is *valid* in a matrix *M* if it holds on every *M*-evaluation. We will not use the term 'tautologous sequent' (or 'tautology', in the case of FMLA) except for the special case of validity in the familiar two-element matrix. For this special case, also, we do not need the distinction between valuations and evaluations. The set of sequents determined by a class of matrices comprises precisely those sequents valid in each matrix in the class: such a set will always be a logic (as defined above). A logic determined by the class $\{M\}$ will be said to be determined by the matrix *M*. Notice that the logic in FMLA determined by the 1-Kleene matrix (which differs only from Łukasiewicz in that $2 \to 2 = 2$) is just the empty set, the assignment of the value 2 to every formula being an evaluation for this matrix. Since Łukasiewicz worked in FMLA, this is one reason that in his tables we have $2 \to 2 = 1$ (rather than $= 2$). (The logics determined by the Kleene matrices in the other frameworks are of course non-empty.)

3 Logic (cont.)

We say a logic is 'many-valued in the narrow sense' when it is determined by some matrix, and 'many-valued in the broad sense' when it is determined by some class of matrices. In FMLA this is a distinction without a difference, an early result of Lindenbaum and Tarski having established that in this framework every logic is many-valued in the narrow sense. However, in the case of the other frameworks, the distinction is a real one.

In SET-FMLA, for example, every logic closed under certain structural rules ('overlap', 'dilution' and 'cut' (for sets) - see Shoesmith and Smiley 1978) is broadly many-valued. We call a relation '$\vdash$' between sets of formulas and individual formulas (of some given language) a consequence relation (on that language) when there is some collection Σ of sequents of SET-FMLA which is closed under the SET-FMLA structural rules and for which we have $\Gamma \vdash A$ if and only if the sequent $\Gamma \succ A$ belongs to Σ. (This means that '$\Gamma \succ A$' is treated as an alternative notation for $\langle \Gamma, A \rangle$.) Closure under these structural rules is a necessary condition for a logic to be determined by any class of valuations. These same rules must be satisfied by any logic determined by a class of matrices for the following reason. Given an *M*-evaluation *h* (for some matrix *M*), we define the (bivalent) valuation v_h induced by *h* thus: $v_h(A) = \mathrm{T}$ if and only if $h(A) \in D(M)$, for all formulas *A*. Then a sequent holds in the many-valued sense on *h* just in case it holds, in the bivalent sense, on v_h. Accordingly a set of sequents is determined (many-valued sense) by a class $\mathbb{C}$ of matrices precisely when it is determined (bivalent sense) by the class of valuations $\{v_h\colon h$ is an *M*-evaluation for some $M \in \mathbb{C}\}$. Thus the structural rules must also be satisfied by

any SET-FMLA logic which is many-valued in the broad sense. Now while a necessary and sufficient condition for a logic in SET-FMLA to be many-valued in the broad sense is that it should be a consequence relation, there is a further condition to be satisfied in the case of the narrow sense, which is called the cancellation condition in Shoesmith and Smiley (1978). (See also Wójcicki 1974.) This further condition is not satisfied in the case of the consequence relation determined by the pair comprising the 1-Kleene matrix and the 1,2-Kleene matrix, for example, which is not, therefore, a many-valued logic in the narrow sense.

Note that the narrow sense could be further narrowed to exclude determination by a two-element matrix: it is only on such a usage that Łukasiewicz could be counted a pioneer of many-valued logic, for example. A further narrowing in the 'opposite' direction comes by disallowing determination by an infinite matrix to suffice for many-valuedness. The motivation for excluding infinite matrices comes from more than one source. Philosophically, there may be a feeling that such a case involves too many distinctions for the values so distinguished to represent a plausible generalization of the idea of truth-values (Haack 1978: 214). Perhaps the assignment made by an evaluation in this case is better thought of as the assignment of a 'proposition' to a formula (see Dunn 1975). There is also a technical pressure tending towards excluding the infinite case, coming from the Lindenbaum-Tarski result mentioned above together with an early concentration on the framework FMLA: since *every* logic is many-valued in the absence of the restriction to finite determining matrices, we might impose this restriction to avoid making the term 'many-valued' vacuous. However, since (again) this threat of vacuity does not arise for other logical frameworks, we prefer not to narrow further the above narrow sense of 'many-valued'. It is better to have a separate word for the property of being determined by a finite matrix; the usual word is 'tabular'.

The first demonstration that a logic was not tabular came when Gödel (1932) addressed this question for intuitionistic sentential logic in FMLA. We can introduce the argument he gave for this conclusion by considering a well-known puzzle. Suppose you have a drawer containing (only) twenty socks, ten of which are blue and ten of which are green. You have to choose a pair of the same colour to wear, but because the room is dark, you cannot see the colours. The question is: what is the smallest number of socks you need to remove in order to be sure that among them there will be a matching pair? And the answer is: (not *eleven* but) *three*. The reason is that, since there are only two colours involved, three socks cannot all be of different colours, so you are guaranteed a matching pair. This is a special case of what is sometimes called the 'pigeonhole principle': if a number of pigeons are to be placed in a smaller number of pigeonholes, then at least one pigeonhole must have more than one pigeon in it.

With the example of the socks in mind, consider the question of whether or not the following formula is a (two-valued) tautology:

$Pigeon_3 \quad (p \leftrightarrow q) \vee (p \leftrightarrow r) \vee (q \leftrightarrow r).$

It should not be necessary to construct the eight-line truth table to answer this question. Since there are only two truth-values (T, F) to go round, no valuation can assign different truth-values to all three propositional variables *p*, *q* and *r*. (The variables here are playing the role of the pigeons - whence the labelling of the formula - with the truth-values being the pigeonholes.) So each valuation must assign the value T to at least one of the disjuncts of the above formula, thus assigning T to the whole disjunction, which is therefore a tautology.

We turn to Gödel's argument that intuitionistic logic in FMLA - which we shall denote by IL - is not determined by any finite matrix. Let CL denote classical sentential logic in FMLA (alias the set of tautologies in two-valued logic). To begin with, let us see how considerations such as those of the preceding paragraph reveal IL to be determined by no three-element matrix, when supplemented by three additional facts: (1) IL $\subseteq$ CL; (2) IL has the 'disjunction property': for all formulas *A*, *B*, if $A \vee B \in$ IL, then either $A \in$ IL or $B \in$ IL; and (3) if *C* is a disjunction one of whose disjuncts is a formula of the form $A \leftrightarrow A$, then $C \in$ IL. (We take '$\leftrightarrow$' as a primitive connective for simplicity here; in fact the whole argument goes through if this is replaced by '$\rightarrow$'.) Now consider the formula

$Pigeon_4 \quad (p \leftrightarrow q) \vee (p \leftrightarrow r) \vee (p \leftrightarrow s) \vee (q \leftrightarrow r) \vee (q \leftrightarrow s) \vee (r \leftrightarrow s).$

This formula is not provable in IL, in view of facts (1) and (2) above. Now suppose that some three-element matrix *M* determines IL. For any *M*-evaluation *h*, fact (3) and the pigeonhole principle imply that $Pigeon_4$ holds on *h*, since *h* cannot assign distinct *M*-elements to all four propositional variables. Thus, though not IL-provable, $Pigeon_4$ is *M*-valid: so IL is not determined by *M*. The same argument shows (by analogous consideration of the

formula we naturally call $Pigeon_n$) that, for any finite number *n*, IL is not determined by any matrix having *n* elements: IL is not tabular.

4 From evaluations to valuations

Our introduction, in §3, of the valuation v_h induced by a matrix evaluation *h*, serves as a reminder of the twofold division which is always present in the background of the many-valued setting, in the form of the ubiquitous designated/undesignated distinction. The notion of validity for sequents is always a matter of invariable possession or preservation of truth: of T as a value of the functions v_h. Distinctions within the classes of designated and undesignated matrix-values do not matter for validity, and enter the semantic account only because the connectives concerned cannot be seen as simply 'designation-functional': in the case of Łukasiewicz's and Kleene's three-valued tables, for example, while $h(\neg A)$ is uniquely determined by $h(A)$, there is no such unique determination of $v_h(\neg A)$ by $v_h(A)$. So we do our compositional semantics at the level of evaluations, and then modulate to valuations for talk of validity.

Here is an analogy: imagine that chemistry were concerned in the first instance with the colours of chemical compounds. We would like to know what colour a compound of substances of given colours will be. The trouble is that just knowing what colour the constituents are is not enough to tell us what colour the compound will be. We also need to know about their chemical composition, so that this extra information can be used to predict the eventual colour of the compound, via its chemical composition. Similarly, even if all we are interested in knowing about a composite formula *A* # *B* (where # is some binary connective) is whether or not it has a designated value on evaluation *h*, we cannot obtain this information - that is, the value of v_h(*A* # *B*) - just from knowing $v_h(A)$ and $v_h(B)$ (the 'colours' of *A* and *B*). Rather, we need to know $h(A)$ and $h(B)$, so that we can apply our matrix operation # to these values and obtain *h*(*A* # *B*), and then, eventually, v_h(*A* # *B*). This is precisely to acknowledge the possibility of a failure of what was called designation-functionality above.

But are the subdivisions effected by the apparatus of many-valued logic of merely instrumental interest? Such a suggestion has been elaborated over a long period by Michael Dummett, beginning with his article 'Truth' in 1959. The problem Dummett noted is that when we consider the point of the true/false dichotomy as applied to whole sentences (of an interpreted language such as English) which might be used to make assertions, there does not seem to be room for alleging any particular sentence to fall on neither side:

> We need to distinguish those states of affairs such that if the speaker envisaged them as possibilities he would be held to be either misusing the statement or misleading his hearers, and those of which this is not the case: and one way of using the words 'true' and 'false' would be to call states of affairs of the former kind those in which the statement was false, and the others those in which the statement was true.
>
> ([1959] 1978: 11-12)

Dummett went on to describe in the light of this criterion how particular cases in which statements have been described as neither true nor false should be classified as true or as false, depending on the nature of the case. The various values of many-valued matrices are then seen as subdivisions of the true (the designated values) and the false (the undesignated) - different ways of being true or of being false, the difference between which needs to be taken into account for settling how the fundamental binary true/false distinction is to apply to compounds into which they enter as components. We repeat one of Dummett's illustrations:

> I once imagined a case in which a language contained a negation operator '$-$' which functioned much like our negation save that it made '$-(A \rightarrow B)$' equivalent to '$A \rightarrow -B$', where '$\rightarrow$' is the ordinary two-valued implication. In this case, the truth or falsity of '$-(A \rightarrow B)$' would not depend solely on the truth or falsity of '$A \rightarrow B$', but on the particular way in which '$A \rightarrow B$' was true (whether by the truth of both constituents or by the falsity of the antecedent). This would involve the use of three-valued truth tables, distinguishing two kinds of truth. In the same way, it might be necessary to distinguish two kinds of falsity.
>
> ([1963] 1978: 155)

Indeed, Dummett (1959) suggested this last possibility as the appropriate gloss on the response of those who describe sentences containing non-denoting singular terms as 'neither true nor false'. The response is a natural one if one thinks of falsity of a sentence as the truth of its negation (supposing the identification of a sentence's

negation is not itself problematic), but since it would be equally erroneous ('misleading') to assert either the given afflicted sentence or its negation, in terms of the more fundamental true/false dichotomy, both sentences fall alike on the false side. The two undesignated values of Łukasiewicz's three-valued logic can be regarded in the same light: as cases in which a sentence having either value are not, the facts being what they are, fit for assertion. They differ in respect of whether the negation of the sentence in question suffers the same fate (according to Łukasiewicz's metaphysical assumptions, that is, and setting to one side the problems about truth-functionality mentioned in §1).

It is for reasons such as this that Dummett speaks of 'the legitimate but comparatively superficial character of the rejection of the law of bivalence involved in the use of a many-valued logic' (1973: 448). In the same work, Dummett draws a distinction between the 'assertoric content' and the 'ingredient sense' of a statement, introduced in terms of the distinction between knowing the meaning of a statement 'in the sense of grasping the content of an assertion of it' and 'in the sense of knowing the contribution it makes to determining the content of a complex statement in which it is a constituent' (1973: 447). Sentences (or statements) which are alike in respect of assertoric content are true (that is, have some designated value) under the same conditions, which does not imply that the replacement of one by the other in some complex sentence will secure a similar likeness for the two complex sentences produced. When the complex sentences differ in respect of designation in this way, the components in respect of which they differ themselves differ in ingredient sense, their similarity of assertoric content notwithstanding. Thus, in terms of our formal notation, and slightly oversimplifying, equality of ingredient sense, for *A* and *B*, corresponds to having $h(A) = h(B)$ for every matrix-evaluation *h*, while equality of assertoric content corresponds to having $v_h(A) = v_h(B)$ for each such evaluation *h*.

Dummett's rationale for many-valued (that is, *k*-valued for $k > 2$) logic, then, is that there is sometimes a need to record differences in ingredient sense among statements which do not differ in assertoric content. Without going into too much technical detail, though, we can see that this is not quite accurate. We call a consequence relation '$\vdash$' 'extensional' if for all formulas *A*, *B*, with $C(A)$ and $C(B)$ the results of putting formulas *A* and *B* into some context *C*, and for all sets Γ of formulas, we have

If $\Gamma,\ A \vdash B$ and $\Gamma,\ B \vdash A$, then $\Gamma,\ C(A) \vdash C(B)$;

and we call '$\vdash$' 'congruential' when the above condition is satisfied by all *A*, *B*, *C* for the special case in which $\Gamma = \emptyset$. Congruentiality is strictly weaker than extensionality (consider normal modal logics, for example) and, as the end of the last paragraph makes clear, the need to distinguish ingredient sense from assertive content arises precisely when the logic (in SET-FMLA, for expository convenience) is not congruential. Yet, as the reader may care to check, it is failures of the stronger condition, extensionality, rather than just failures of congruentiality, that force a matrix treatment to involve more than two values.

5 From evaluations to valuations (cont.)

We end by briefly taking up one further issue raised by the above exposition: the case of intuitionistic logic. A perusal of Dummett (1959) reveals that his talk (quoted above) of the 'superficial character of the rejection of the law of bivalence' in many-valued logic is intended to contrast with the 'deeper' character of such a rejection in the case of intuitionistic logic. One reason for not considering intuitionistic logic to be many-valued seems hardly to the point here: namely the fact that, as we saw in §3, intuitionistic logic in FMLA is not determined by any finite matrix. (Nobody questions the classification of Łukasiewicz's infinite-valued logic as many-valued, for example.) By the Lindenbaum-Tarski result cited in that section, this ceases to be the case if 'finite' is deleted. Turning to SET-FMLA, the consequence relation associated with intuitionistic logic satisfies the cancellation condition (alluded to in §3) and so here too there is a single determining matrix. On formal grounds, then, we have to say that intuitionistic logic in either of these frameworks is indeed many-valued in the narrow sense of the term. Cardinality of determining matrices aside, are there any good reasons for not regarding IL as many-valued? There is a sense of 'many-valued' which we have not touched on, which allows an affirmative answer to this question: but it has more to do with what its adherents say about a logic than with the logic itself. The usual sort of reason for denying that IL is many-valued is that it would be inconsistent, according to IL itself, for an intuitionist to claim of some given statement that it was neither true nor false - at least when the falsity of *A* is identified with the truth of $\neg A$. (This use of 'falsity' is of course not that focused on in the quotation from Dummett (1959).) For

such a claim would then be of the form $\neg(A \vee \neg A)$, or, IL-equivalently, of the form $\neg A \wedge \neg\neg A$: but the negation of anything of this form is itself IL-provable. So the claim is not one an intuitionist could consistently make. The trouble with this as a way of distinguishing IL from a paradigmatically many-valued logic such as Łukasiewicz's three-valued logic is that dangerously similar moves can be made in the context of the latter logic also. If, instead of adopting an external perspective and saying that *A* is a statement which is neither true nor false, we think of representing such a claim as the claim that for the given *A* (which concerns, say, someone's later free actions), $\neg(A \vee \neg A)$, then again we have the equivalence with $\neg A \wedge \neg\neg A$, and this time the further equivalence with $\neg A \wedge A$. And while the negation of the latter is not provable in Łukasiewicz's logic (so that here we have a disanalogy with the case of IL) it remains the case that nothing of that form can receive the designated value on any matrix evaluation: so it is presumably after all not the kind of claim anyone attracted to Łukasiewicz's revision of classical logic ought to be making. As in the case of IL, such a theorist is distinguished from an adherent of classical logic by refraining from making certain claims (for example, some having the form $A \vee \neg A$), rather than by trying to make contrary claims. Further work, then, is called for on the part of anyone wishing to maintain that in some philosophically significant sense Łukasiewicz's logic is many-valued while that of the intuitionists is not.

Marcel, Gabriel (1889-1973)

Marcel was a distinguished French playwright and music critic as well as philosopher. It was he who coined the term 'existentialism', although he was reluctant to be pigeon-holed a 'Christian existentialist'. Born into a well-off family of civil servants, Marcel - never a healthy man - worked for the Red Cross during the First World War, an experience which shaped his view of human relationships and confirmed a religious conviction that led to conversion to Roman Catholicism in 1929. After an early flirtation with F.H. Bradley's idealism, Marcel independently developed a phenomenology of human existence and a religious conception of being similar, in several respects, to those of Karl Jaspers and Martin Buber. He was much in demand as a lecturer in his later years.

Marcel was an idiosyncratic writer. Disavowing any 'system', his early writings were ruminative diaries, while his later lectures largely consisted in 'orchestrating', as he put it, the themes tentatively announced in those diaries. The personal anecdotes, of his wartime work for example, testified to his belief that reflection on certain experiences - of 'homelessness' and 'hope', for instance - is a key to understanding our place in the universe. Indeed, they reflect his sense, shared with other existentialists, of 'the primacy of being over knowledge' ([1933] 1949: 8), and his denunciation of 'the execrable habit of considering problems…in abstraction from…the very texture of life' ([1935] 1949: 102). Marcel describes his philosophy as a 'concrete' one, and as a true empiricism distinguished by a refusal to follow most empiricists in their myopic focus on *perceptual* experience.

Marcel's ambition was 'to restore its ontological weight to human experience' ([1935] 1949: 103). Restoration is required because human beings now live in - to cite the title of his best-known play - 'a broken world', where they have been reduced to mere 'functions' by the levelling processes of modern technology and politics. As such, while people feel alienated or homeless, they have all but lost the capacity to reflect on their existence and its relation to being at large. A main reason is the predominance of scientific thinking, which reduces all questions to 'problems' with 'technical' solutions, thereby obscuring the sphere of the 'metaproblematic' or 'mysterious'. A 'mystery' is something I am so 'caught up' in that objective analysis, which presupposes a sharp distinction between myself and what is 'in front of me', is inappropriate. For being is precisely what 'withstands…exhaustive analysis..[into] elements…devoid of intrinsic significance' ([1933] 1949: 5), so scientific thought is hostile to ontology, to inquiry into being.

A main culprit behind the hegemony of problem-centred thinking has been philosophies, like Cartesianism, which portray the self as an inner, closed-in sphere 'spectating' a world outside it. This has encouraged the views that the mind is distinct from the body, that we perceive internal data which 'translate' external stimuli, and that 'other minds' need to be inferred from perceptual data. The general effect is to promote the image of myself standing to the world as a 'subject' to an array of 'objects'. Against this, Marcel insists that 'I am not watching a show', that 'ours is a being whose…essence is to be in every way *involved*' ([1935] 1949: 21, 116-17). I am not distinct from my body as a participating agent in the world. Perception is not awareness of inner data, but active 'reception' of the world, a 'power of opening oneself' to it ([1940] 1964: 29). And in relations like love, other persons are directly 'present' to me, not phantoms whose existence I infer from their behaviour. Marcel's is 'a metaphysic of *we are* as opposed to a metaphysic of *I think*' ([1950b] 1951: 9).

While Cartesianism and its relatives are philosophical errors, it is depressingly familiar in our 'broken world' to live as if they were true, like the solipsistic figures in Proust's later volumes. Marcel's task is to summon us to a 'secondary reflection' which 'reconquers [our] unity' ([1950a] 1950: 103) with the world and each other, one broken by the 'primary reflection' of analytical science, and thereby to free us from the 'sclerosis' which confines us within narrow 'concentric zones'. In particular, he summons people to be 'available' (*disponible*), a stance best manifested in absolute 'fidelity' or commitment to others. Far from sacrificing individuality and freedom through being 'available' to others, this is the only way to achieve them. Not only can I 'really know myself only when I have committed myself' to others ([1940] 1964: 163), but it is only through 'collaboration with his freedom' - through our mutual acknowledgement of one another as 'Thou' - that I myself attain freedom ([1935] 1949: 107). (Marcel, predictably, is acutely critical of Sartre's bleak and agonistic portrait of human relations in *Being and Nothingness*).

Marcel indicates, however, a potential paradox in the making of absolute commitments to others. Given the uncertainty of the future, how for example can a man, unless naïve or disingenuous, commit himself to a lasting loving relationship with his wife? The solution is that he must place hope and faith, if not precisely in God 'as someone other', then at least in a mysterious and co-operative process of being. Thus mundane fidelities only 'become possible…with that absolute fidelity which [is] faith' ([1940] 1964: 167). Indeed, in the intimations of hope and confidence for the future resides the best testimony to a divine, mysterious order. The traditional proofs for God's existence are of little interest to Marcel, since even if they cannot be logically faulted, they clearly have no power to convince people not already predisposed to belief. He remains hesitant, however, over the need for specifically Christian belief for the possibility of 'availability' and 'fidelity'. On the one hand, this does not logically 'presuppose the data of Christianity'; on the other, we are the legatees of a rich Christian tradition which may, as a matter of fact, provide us moderns with our only viable resources for full and undespairing participation in the world and the lives of our fellows ([1933] 1949: 29f).

Marcus Aurelius (AD 121-80)

Marcus Aurelius Antoninus, Emperor of Rome, was the author of a book of philosophical reflections written in Greek and known as the Meditations. These reflections are based primarily on Stoicism, but also reveal the influence of other currents of thought and of his experience as emperor. Marcus was deeply influenced by Epictetus and shares his interest in the inner mental life and the psychology of moral improvement. He combines a deep commitment to the providential cosmology traditional in the Stoic school with a more pronounced religious sensibility and a frequent emphasis on the insignificance of human life in space and time. The Stoic recognition of the irreducibly social character of human nature is obviously pertinent to an emperor whose career consisted largely of self-sacrificing public service.

1 Life

Marcus was born in Rome in AD 121, was adopted by the future emperor Antoninus Pius in 138, and succeeded to the throne (jointly with Lucius Verus) in 161. In 169 Verus died, leaving Marcus sole emperor until 177 when his son Commodus joined him. Marcus died on campaign.

Marcus was the last in a series of efficient and humane emperors chosen by adoption whose reigns made the second century AD the high point of Roman imperial culture. The stability of this culture was threatened, however, by military challenges, and Marcus' reign was beset by wars on its borders. (It was during these campaigns, late in his life, that Marcus composed the notebooks which were published after his death.) The reign of his son Commodus was unsuccessful; his assassination in 192 ushered in a period of uncertainty which ended with the consolidation of the rule of Septimius Severus in 197. It is tempting to regard Marcus' reign as the acme of the Roman system and to assign Marcus much of the credit. But the seeds of decay were already present and Marcus did little to prevent the decline.

As a member of the ruling elite, Marcus was educated in Latin oratory and in law, but he also had Greek tutors, including the 'sophist' Herodes Atticus. Marcus' mentor in Latin was Marcus Cornelius Fronto, one of the most famous literary figures in Rome. Fronto's influence on Marcus was personal as well as literary and the correspondence (in Latin) between them rounds out the picture of Marcus which we get from his philosophical writings.

To the disappointment of Fronto, Marcus chose the study of philosophy (which he had begun under the Stoic Apollonius) over law and oratory. The catalyst for this choice was Quintus Junius Rusticus, who not only provided a model of philosophical principle applied in public life, but also introduced Marcus to the *Discourses* of Epictetus (*Meditations* I 7). Marcus' personal circle included philosophers of various schools, some of them active in the administration of the empire. He describes Claudius Severus, a Peripatetic, as 'brother' and credits him with inspiration in the area of political theory and practice; Severus introduced Marcus to the ideas of Thrasea Paetus and other figures of the philosophical opposition to Nero (I 14). Severus may be responsible for Marcus' acceptance of the un-Stoic denial of the equality of moral errors (II 10) (see Stoicism). Another influence was Marcus' friend Claudius Maximus, a political and military leader as well as a (possibly Peripatetic) philosopher (I 15); yet another friend, Cinna Catulus, was probably a Stoic (I 13). A certain Alexander, a Platonist, was given a key political post (Greek secretary) at a time of crisis (I 12). Perhaps the best insight into Marcus' philosophical formation comes from reflection on his relationship with Sextus of Chaeronea, a professional philosopher and nephew of Plutarch of Chaeronea. Marcus continued to attend Sextus' lectures even while emperor; in the *Meditations* (I 9.1) Marcus says that he learned from this Platonist the meaning of 'life according to nature' - the defining slogan of the Stoic school (see Stoicism §17). This same philosophical breadth is reflected in Marcus' establishment of the first ever chairs of philosophy. In AD 176 he endowed four chairs at Athens, one for each of the recognized major schools - Platonism, Aristotelianism, Stoicism and Epicureanism.

2 The *Meditations*

The *Meditations* reflects this lack of school dogmatism. While Stoicism provides the framework, Platonic and other ideas are also accommodated. Marcus' philosophical importance does not lie in the preservation or development of the Stoic system but rather in his demonstration of its adaptability to various circumstances and

philosophical temperaments.

The framework for Marcus' thought is providential cosmology. The cosmos is an organic whole; each individual is not just a part of that whole, but a limb or organ of the living universe (VII 13). Our well-being is inseparable from that of the whole; he frequently calls humans mere 'fragments' of it. We are similarly related to human society: our private benefit can never conflict with that of the collectivity. Our human nature is fundamentally social; personal fulfilment can never be achieved at the cost of the welfare of the whole. This idea is made into a test of what counts as harm to an individual: 'what is not harmful to the city does not harm the citizen either' (V 22). Civic welfare subsumes, but does not negate, that of the individual. Marcus emphasizes the Stoic claim that whatever happens by nature is in the best interests of each rational agent, that nothing genuinely bad can befall anyone except by way of their own failings. The conjunction of providential determinism with an emphasis on our role as parts of an organic whole brings Marcus close to the *amor fati* ('love of fate') of which Stoics are often accused.

Marcus' conception of the true interests of each person rests on the Socratic idea that nothing bad can happen to any good person. Also Socratic are his determination to teach, not punish, the wrong-doer (everyone should be forgiven, since all are aiming at their own good - XI 16) and the notion that a happy life is based on critical examination of one's convictions. This reveals, he thinks, that nothing unexpected or unbearable ever happens to a rational person (V 18). Like Epictetus, he emphasizes the role of mental reservation (IV 1, V 20), the analysis of impressions, and impersonal detachment; the one thing which ultimately matters is our mental life, our desires, beliefs and convictions.

If the cosmos subsumes individual well-being, then each of us is transient, important only for the rationality we embody, a rationality identified with an indwelling divinity. Hence Marcus emphasizes the smallness of human life, that we are a mere point in space and time (for example, XII 32). The inevitabilty of material change and the cyclical certainty of birth and death are themes to which Marcus returns repeatedly, often drawn from Heraclitus imagery; nothing as predictable as our own deaths can be regarded as important. Hence there are no surprises for anyone who has spent even half a lifetime in critical reflection on the world (XI 1.2); the most important thing is to structure one's beliefs around the rationally inevitable. Another link between cosmology and ethics emerges from Marcus' repeated reflection on Epicurean atomism - a system opposed to the providential cosmology shared by Platonists and Stoics (see X 6). He states the case tersely at XI 18.1: 'If not atoms, then there is a nature which organizes the universe; and if this is the case, then the inferior exist for the sake of the superior, and the superior [that is, rational beings] for the sake of each other.'

Marcus' views on the composition of human beings can be singled out as an illustration of his openness to non-Stoic influences. We are made up of three components (XII 3): body, 'spirit' or *pneumation*, and intelligence (Nous, identifiable with an internal divinity); although we must care for all three aspects of ourselves, only the third is really our own. The separation of *pneuma*, the stuff of the entire soul according to traditional Stoic theory (see Pneuma), from our rationality is a mark of Platonic influence; this *pneuma* is associated by Marcus with automatic, puppet-like responses. If our reason is separable from the rest of our soul and from our body, then our personal identity has been detached from our empirical selves and the early Stoic unity of the person has been abandoned. Hence Marcus says: 'Wipe out impression; stop your impulse; extinguish desire; keep your commanding-faculty (*hēgemonikon*) in your own control' (IX 7). The similarity to Epictetus is limited. For Marcus, to set impulse, impression and desire in opposition to the commanding-faculty appears as a step on the road to Neoplatonism (see Neoplatonism).

But Marcus never abandons the foundations of Stoic physical theory. He repeatedly claims that everything is either 'material' or 'causal' (V 13, VII 29, VIII 11, IX 37, XII 29). Though the terminology is new (it is also reflected in Seneca, *Letters* 65.2), this is the same physical dualism which Zeno of Citium and Chrysippus employed when they divided the universe into the active and passive principles and identified the former with a rational divinity (see Stoicism §§3, 5). Building on this, the founders of Stoicism had outlined a cosmology in which divine guidance and rational coherence were integral parts of the natural world. Despite the appeal of Peripatetic and especially Platonic thought, Marcus retained a Stoic commitment to a unified and physicalist conception of the natural world. Marcus the emperor clung tenaciously to the political and military stability of the second century AD, but he was the last to do so. Similarly, Marcus the philosopher clung to his Stoic tradition.

Marcuse, Herbert (1898-1979)

Herbert Marcuse endured a brief moment of notoriety in the 1960s, when his best-known book, One-Dimensional Man (1964), was taken up by the mass media as the Bible of the student revolts which shook most Western countries in that decade. Though Marcuse's actual political influence was uneven, his public image was not wholly misleading. On the one hand, he popularized the critique of post-war capitalism that he, with the other theorists of the Frankfurt School, had helped develop: the Western liberal democracies were, they argued, 'totally administered societies' permeated by the values of consumerism, in which the manufacture and satisfaction of 'false needs' served to prevent the working class from gaining any genuine insight into their situation. On the other hand, Marcuse never fully subscribed to the highly pessimistic version of Marxism developed by the central figures of the Frankfurt School, Adorno and Horkheimer. He hoped that revolts by an underclass of 'the outcasts and the outsiders, the exploited and persecuted of other races and other colours, the unemployed and unemployable' would stimulate a broader social transformation. Underlying this affirmation of revolutionary possibilities was a conception of Being as a state of rest in which all conflicts are overcome, where rational thought and sensual gratification are no longer at war with one another, and work merges into play. Intimations of this condition - which could only be fully realized after the overthrow of capitalism (and perhaps not even then) - were, Marcuse believed, offered in art, 'the possible Form of a free society'. Imagination could thus show politics the way.

1 Life

Marcuse was born in Berlin. Like many young intellectuals of his generation, he was radicalized by his experience of the First World War, and, as a soldier stationed in Berlin, took part in the Revolution of November 1918. Though he studied Marxism during and after the war (when he went to Freiburg University), Marcuse was never involved in the Communist movement. After reading *Being and Time* soon after its publication in 1927 Marcuse returned to Freiburg to work under Martin Heidegger. His early philosophical writings represented a remarkable attempt, as he later put it, 'to combine existentialism and Marxism', though Marcuse later turned against what he came to think of as the 'false concreteness' of Heidegger's philosophy (see Existentialism). The main work of this period was Marcuse's *Habilitationsschrift*, the dissertation submitted to obtain the right to teach in German universities. Originally called *Hegel's Ontology and the Foundations of the Theory of Historicity* and completed in 1932, this text was (accounts differ) either never formally submitted or rejected by Heidegger on political grounds.

Marcuse left Germany in December 1932, a few weeks before Hitler came to power. Thanks to the help of, among others, Edmund Husserl (another of his teachers at Freiburg), he was invited to join the Institute for Social Research, which had left its base at Frankfurt University to take refuge in Geneva. Marcuse followed the Institute to Paris and then, in July 1934, to New York, and became one of its most active theorists, publishing a series of major essays in its journal, the *Zeitschrift für Sozialforschung*. Marcuse's active collaboration in the collective work of the Frankfurt School culminated in his second major study of Hegel, *Reason and Revolution* (1941).

Somewhat ironically, in the light of his later notoriety, Marcuse worked in the Office of Strategic Services, the predecessor of the Central Intelligence Agency, between 1942 and 1950. Unlike Horkheimer and Adorno, he did not return to Frankfurt after the Second World War, but became a US citizen. After holding research posts at Columbia and Harvard, Marcuse taught at Brandeis University from 1954 till his retirement in 1965. During these years he wrote *Soviet Marxism* (1958) and his two most influential books, *Eros and Civilization* (1955) and *One-Dimensional Man* (1964). Between 1965 and 1970 Marcuse held a series of temporary appointments at the University of California at San Diego. It was then that he became an international figure, thanks to his depiction in the mass media as the intellectual author of the radical student movement of the late 1960s. Though this was grossly exaggerated (two leaders of the French student revolt in May 1968 declared, 'None of us have read Marcuse'), Marcuse did make clear his sympathy with the students. In this respect he was quite different from Horkheimer and Adorno, who became increasingly conservative as they grew older. Marcuse's most important later works were perhaps *An Essay on Liberation* (1969) and *The Aesthetic Dimension* (1978). Taken ill during a lecture tour of Germany, he died at Starnberg.

2 Eros and capitalism

Marcuse's starting point, like that of the other leading figures in the Frankfurt School, was provided by the two decisive moves taken by Georg Lukács in *History and Class Consciousness* (1923). First, he developed Marx's theory of commodity fetishism into a general critique of reification (see Marx, K.). Capitalist society, Lukács claimed, seemed to its participants to be a collection of fragments; while individuals might adopt the instrumentally rational means to achieve their particular ends, they lacked any well-founded understanding of the social whole. Second, Lukács identified a unique vantage-point from which such understanding could be gained - that of the proletariat, conceived less as an empirical social class than as the 'identical subject-object' of history, able because of its reduction to the status of a commodity to grasp the meaning of the whole as it strove towards the revolutionary overthrow of capitalism.

The Frankfurt School was enormously influenced by Lukács's theory of reification, but found the idea of the proletariat as a stand-in for the Hegelian Absolute quite implausible. The result was the radical pessimism of Horkheimer's and Adorno's *Dialectic of Enlightenment* (1947), where liberal-democratic capitalism is depicted as a seamless web of reification, as implicitly totalitarian as its fascist and Stalinist opponents were openly, and the rise of instrumental reason is traced back to the first efforts of human beings to control nature. Reason is inextricably implicated in the domination of both nature and human beings. The task of critical theory (as the Frankfurt School tended to call their version of Marxism) is henceforth a negative one, endlessly to expose the unreconciled and unjust character of prevailing society, rather than to identify and promote tendencies leading to social transformation.

Marcuse managed to be part of this evolution, yet remain apart from it. On the one hand, *One-Dimensional Man* is in many ways a popularized and updated *Dialectic of Enlightenment*. Post-war capitalism, Marcuse argues, has overcome any tendency towards economic crisis. The attainment of abundance, however, leads not to liberation but to the generation of 'false needs', whose satisfaction leads to 'euphoria in happiness' and prevents individuals from making their decisions autonomously. The working class is in consequence unlikely to play the role assigned it by classical Marxism as the maker of socialist revolution, and has instead become part of the 'conservative social base' of capitalism. These changes are aspects of an emerging 'pattern of *one-dimensional behaviour* in which ideas, aspirations, and objectives that, by their content, transcend the established universe of discourse and action are either repelled or reduced to terms of this action' ([1964] 1968: 27). Critical theory is thereby forced merely to negate existing society. 'In the absence of demonstrable agents and agencies of social change, the critique is thus thrown back to a high level of abstraction' and 'it cannot be positive' ([1964] 1968: 11, 199).

None the less, as Jürgen Habermas observes, there is an 'affirmative feature of Herbert Marcuse's negative thinking' (Habermas 1988). This is perhaps most evident in Marcuse's most original book, *Eros and Civilization* (1955). He seeks to fuse Marx and Freud, drawing especially on the latter's speculative metapsychological writings. Marcuse attempts to diminish the conservative force of Freud's claim that instinctual repression is a constant of human nature dictated by the need for self-preservation. Instead, he argues that the 'performance principle' requiring the denial of sensual gratification is historically variable, changing according to the needs of different societies. Where class domination exists, surplus-repression arises - that is, repression that is required, not for self-preservation, but in the interests of the ruling class. Domination thereby roots itself deep within the unconscious. Consequently, 'from the slave revolts in the ancient world to the socialist revolution, the struggle of the oppressed has ended in establishing a new, "better" system of domination'. Nevertheless, 'the very progress of civilization under the performance principle has attained a level of productivity at which the social demands upon instinctual energy to be spent in alienated labour could be considerably reduced' ([1955] 1969: 75, 101). This offers the prospect of a social revolution which, by abolishing surplus-repression, would release considerable libidinal energies. Marcuse envisages a society in which the conflict between Freud's life and death instincts would be overcome, as they found common ground in an escape from suffering and repression, in a state of calm and repose which would represent a renunciation of what Marx called the realm of necessity, of material toil, a state of affairs in which, as Schiller had anticipated, work would be transformed into play, into 'a productivity that is sensuousness, play and song'.

3 Art and Being

Marcuse's philosophy of history is thus one in which 'the restless labour of the transcending subject terminates in the ultimate unity of subject and object: the idea of "being-in-and-for-itself", existing in its own fulfilment'

([1955] 1969: 88). The reconciling totality which Marcuse posits at the end of history is not, however, Lukács's identical subject-object. 'Being is experienced as gratification,' Marcuse claims of the future society, 'so that the fulfilment of man is at the same time the fulfilment, without violence, of nature' ([1955] 1969: 122-3). The 'ultimate unity of subject and object' is thus one that harmonizes humankind with nature. Marcuse here remains faithful to the Heideggerian interpretation of Hegel which he developed in Freiburg at the end of the 1920s. In *Hegel's Ontology* and related writings he had argued that the most basic category of the Hegelian dialectic is that of Life, conceived as the 'unifying unity of subjectivity and objectivity as a "subjective substance"' ([1932] 1987: 155) - that is, nature must be thought of, not as an aggregate of static objects governed by mechanical laws, but as a single process of continual self-transformation which manages through all these changes, and of which consciousness is simply the most developed form.

Whatever we make of this interpretation of Hegel, which shows the influence of Dilthey as well as Heidegger on the young Marcuse, its appeal to the idea of Life in order to conceptualize the unity of subject and object provides his later writings with their implicit structure and thus helps to explain why he remained, in Martin Jay's words, 'a prophet of identity and reconciliation' (1973). Marcuse believed that contemporary society offered, at its fault-lines, glimpses of 'the repressed harmony of sensuousness and reason'; the 'new sensibility' he discerned emerging in the counter-culture of the 1960s offered one such intimation, as did modern art. Marcuse was fond of quoting Stendhal's definition of beauty as 'the promise of happiness'. The radical minorities which had, in some way or other, come to see through the status quo (and, more important, to live beyond it) were, he believed, 'potential catalysts of rebellion within the majority'. Though such claims resonate with the (to most) hopelessly dated revolutionary hopes of the 1960s, many themes of Marcuse's philosophy - the totalizing power it accords to Life, for example, and the cognitive function assigned to art - recall rather German classical idealism from Schiller to Schelling. Perhaps he is best remembered as one of those (Bloch is another) who tried to continue this tradition in a Marxist idiom.

Marginality

Traditional definitions of marginal persons include those who live in two worlds, but do not feel well integrated into either and those who live in societies which are in the process of being assimilated and incorporated into an emerging global society. The influence of Anglo-American and European cultures has brought this situation into existence. A broader, more contemporary understanding of marginality is the condition of feeling marginal in relation to various concepts of the centre. This state produces a stigmatized identity, which either aspires to inclusion or assimilation into the centre, or demands recognition of and respect for a separate but equal existence. This condition of marginality can be experienced in varying degrees by many kinds of people.

Often gender, sexual preference, age, ethnicity, geography and religion are factors which can influence perceptions of marginality. Those who perceive themselves, or who are perceived by others to be marginal are often female, dark-skinned, very young or elderly, poor, disabled, nonheterosexual, displaced, exiled, immigrant, rural, indigenous, 'foreign', outcast, persecuted, or otherwise 'different' from those who occupy positions of privilege in the centre, or the metropolis. Critics of the term 'marginality' believe it has become overused to the point of losing descriptive precision because, they argue, almost everyone has experienced some form of marginality. In philosophy, however, the phenomenon of feeling, or being, perceived as peripheral, or on the margin, has generated critical perspectives which have enlightened discourse on social integration and stratification; personal suffering and economic, political, and cultural inequality. In addition, analyses of marginality have called into question notions of the 'universal' and the 'objective' set forth by many Western philosophers.

1 Forms of marginality

People who live in two worlds, but do not feel well integrated into either, could include, for example, *Nuyoricans*. This group comprises people of Puerto Rican origin living in New York, who are often perceived as Puerto Ricans or, more generically, as Latinos or Hispanics by other New Yorkers. Nuyoricans are thought of as 'Americanized' by those who live in Puerto Rico and they are considered as traitors to 'real' Puerto Rican culture. The Nuyorican's existence is marginal on the US mainland as well as on the island of Puerto Rico.

Chicanos choose to identify themselves by a name other than Mexican-American to indicate that they are Mexicans with a nonAnglo image of themselves living in the USA. They are not Mexicans who would feel at home in Mexico, with which many of them are unfamiliar, yet neither do they feel assimilated or choose to identify with the mainstream Anglo-American culture they experience in Los Angeles and elsewhere.

Similarly, *black Latinos* often are categorized as, or feel pressurized into identifying with either African-Americans or Latinos, although they do live in both worlds. Immigrants and exiles in general may feel that they live a dual, conflicting existence, as they attempt to maintain familiar cultural traditions which may become increasingly distant while struggling to adapt to new environs and linguistic challenges which some fail to master to their satisfaction.

With the influence of Anglo-American and European cultures those who live in societies which are in the process of being assimilated and incorporated into an emerging global society include people in developing nations, like Africa, Asia and Latin America. Their awareness of dominant or metropolitan cultures is often reinforced by television and imported music. A proliferation of icons of North American popular culture can be found, for example, in the southern Mexican states of Oaxaca and Chiapas, where indigenous peoples have protested against their marginality relative to both Mexico City and the USA. Consciousness of marginality also influences debates in Latin America over which trade agreements would be most beneficial in bringing particular countries closer to the centres of power. A corollary response to the awareness of marginality and the process of assimilation is the rejection of incorporation into a mainstream. Instead, a defence of the interests and traditions of marginal groups and the right of these groups to coexist would be favoured, respecting pieties without adopting one another's values.

The broader condition of feeling marginal in relation to various concepts of the centre, thus possessing a stigmatized identity, is often linked to concepts of otherness and alienation. It should be noted, however, that while

a marginal person may feel alienated, someone who feels alienated is not necessarily marginal. Marginal people are victims of a seemingly immutable, structural alterity. They feel or are made to feel voiceless rather than vocal, powerless rather than empowered, 'barbarous' rather than 'civilized' and unequal rather than equal. They may perceive themselves as subjects rather than as citizens as they often lack the tools, the means and the context to engage in transformational and participatory political processes (see Citizenship). Those whose marginality is not best captured by the earlier definitions of either living in but not belonging to two worlds, or living in an assimilating culture, fit into the alienated world of marginality, or subaltern otherness. Such marginal persons may be female, dark-skinned, very young or elderly, poor, disabled, lesbian, gay, bisexual, transsexual or transgendered, identified with religious or ethnic minorities, rural, or otherwise geographically or ideologically peripheral.

2 Marginality in philosophy

Philosophy produced by thinkers who feel themselves to be culturally or politically marginal is often different in significant ways from philosophy produced by those who perceive themselves as belonging to the 'centre'. This theme is present in the works of recent thinkers such as, James Baldwin, Edward Brathwaite, V.S. Naipaul, Octavio Paz, Adrienne Rich, Edward Saïd, Derek Walcott and Leopoldo Zea (see African philosophy, Anglophone; African philosophy, Francophone; Liberation philosophy; Mexico, philosophy in; Feminist thought in Latin America).

There are in existence metropolitan philosophers, who may or may not be aware of their position of privilege, and there are those who have been 'expelled from the centre of the world and…condemned to search for it through jungles and deserts or in underground mazes of the labyrinth' (1961: 209), as Octavio Paz has indicated. Aristotle maintained that the Greek man was a rational creature capable of governing those who are less rational, such as children, women and slaves. Such a stance testifies that marginality has been a time-honoured tradition throughout the history of Western philosophy. For Leopoldo Zea, marginality is a mechanism whereby one human can deny the other of humanity. One's humanity, in his view, becomes circumstantial, resting on accidents such as skin colour, gender, social class and level of education. Zea refers to the *occidentals*, as opposed to the *accidentals*; Frantz Fanon uses the image of the 'wretched' (1961) and José Ortega y Gasset writes of the existentially 'shipwrecked'. The image offered by Mexican humanist Alfonso Reyes was that Mexican intellectuals would not be invited to the banquet table of Western civilization, although they had many contributions to offer.

3 The value of marginality

Argentine philosopher Arturo Andrés Roig believes that 'The truth is not found primarily in the totality, but in determinate forms of particularity with power to create and recreate totalities from a place outside the latter, as alterity' (1983: 113). Like Roig, most philosophers whose work arises out of marginality and marginalized peoples believe they are testifying that dominant philosophical canons are uninformed or underinformed by the experience of many who are socially and culturally removed from those metropolises in which mainstream philosophers live and think. Leopoldo Zea explains, 'The great Greek, medieval, modern, and contemporary philosophers never had to worry about being original or about their cultures being strange since both their cultures and the people who created these cultures were considered universal' (1971: 15). Zea maintains that the problem of philosophy in Latin America 'is the awareness that its existence is a marginal existence' (1971: 19).

However, being marginal is not necessarily a negative intellectual phenomenon. On the contrary, there is an ironic sense in which the philosophy of marginality is a gift from the centre to the margin. Marginality is a gift to philosophers who live and think on the margin in the sense that it affords them a certain latitude to make original contributions in areas that have been ignored through the undetected or unimagined provincialism of the mainstream. Marginality becomes a methodology which challenges how and by whom values are grounded to such an extent that marginal thinkers believe that their viewpoint offers a vantage point that better illuminates and more comprehensively grounds values.

Philosophy from the margin more easily lends itself to self-criticism, in opposition to philosophy from the centre which has no pressing need to criticize itself precisely because it represents the centre, or universal. Therefore, marginal philosophy can be more thought-provoking and compelling.

Maritain, Jacques (1882-1973)

Maritain was one of the most influential twentieth-century interpreters of the thought of Thomas Aquinas. His interests spanned many aspects of philosophy, including aesthetics, political theory, philosophy of science, metaphysics, education, liturgy and ecclesiology.

His acknowledged masterpiece is The Degrees of Knowledge (1932). In this work, Maritain expands on Thomistic thought and seeks to explain the links between philosophy, science and religion as branches of wisdom. Rather than being a close study of Thomism, this work expands on Thomistic ideas and puts them into the context of the modern world. In natural science, for example, he distinguishes between empirical knowledge of nature and philosophy of nature; the latter consists in the knowledge of essence, while the former is concerned with the knowledge of form.

In moral philosophy, Maritain expands on Aquinas, holding that no true conception of the human ultimate end is philosophically possible, and that moral philosophy therefore must be subordinated to moral theology. Later in his career, Maritain concentrated more strongly on theology, but throughout his life his Roman Catholic faith informed all of his works. He continues to be read widely today, with a worldwide reputation which is especially strong in France and North America.

1 Life

Jacques Maritain was one of the two or three most prominent Thomists during the long second phase of the revival of study of St Thomas Aquinas. It is difficult to think of an area of philosophy to which he did not devote himself. His first book appeared in 1906 and his last in the year he died. He lived through the period when Thomism was established throughout the Catholic world and survived into a post-conciliar period when that effort came under acute criticism.

Maritain was born in Paris in 1882. In 1900, while a student at the Sorbonne, he met Raissa Oumansov, a fellow-student; they were true soul mates, and were married in 1902. After their conversion to Catholicism, it was Raissa who first discovered St Thomas Aquinas. Their home in Versailles became a place where artists, authors, philosophers and theologians gathered. When they moved to Meudon in 1923, these meetings were formalized as the *Cercle d'Études Thomistes*. Maritain's *Prayer and Intelligence* (1922) sets forth the complementarity of the spiritual and intellectual lives.

Maritain taught first at the Lycée Stanislas, then at the Institut Catholique, but his thought and writings were not driven by academic duties. He first visited North America in 1933, and returned there in 1938. Étienne Gilson had hoped to enlist Maritain as a permanent associate at the Pontifical Institute of Mediaeval Studies in Toronto, but Maritain proved elusive. He became a frequent lecturer at Chicago and Notre Dame, and was with his wife in the United States when France fell in 1940; they remained until 1944, when Jacques was named French Ambassador to the Vatican. Raissa's two volumes of memoirs, *We Have Been Friends Together* and *Adventures in Grace*, acquainted a generation of Americans with their dramatic story, their friends, and the burgeoning Catholic culture of France.

Maritain served as the president of the French delegation to UNESCO during the drafting of the Universal Declaration on Human Rights, but resigned as ambassador to accept an appointment at Princeton in 1948. The Maritains returned to France in 1960, where the ailing Raissa died. Jacques settled in Toulouse, where he taught philosophy and theology to the Little Brothers of Jesus. In 1965, at the close of the Second Vatican Council, Paul VI presented Maritain with a message addressed to intellectuals. Maritain divided his time between Toulouse and Kolbsheim near Strasbourg. In 1970, this quintessential layman entered the religious life as a Little Brother of Jesus. He died in 1973 and is buried with Raissa at Kolbsheim.

2 Thomism

In *Aeterni Patris* (1879), Leo XIII called for a renewal of Christian philosophy, particularly that of St Thomas Aquinas, as a way of combating modern errors. The response to the encyclical occurred in stages, eventually fanning out across the globe. Journals were founded, new institutes and associations were formed, conferences

were held, and there was a flood of interpretations and prolongations of the thought of Aquinas. At first a largely clerical phenomenon, the Thomistic revival became, with Maritain and Étienne Gilson, a lay effort which more effectively related traditional Catholic thought to the wider culture.

Maritain, like so many of his generation, came under the influence of Henri Bergson, whom he examined in comparison with Aquinas in his first book, *Bergsonian Philosophy* (1913). *Antimodern* (1922) might suggest that Maritain saw Thomism simply as antithetical to contemporary thought, but that this was not his view is clear from *Angelic Doctor* (1929), as well as earlier works. However, the most comprehensive statement of his philosophical vision is given in *The Degrees of Knowledge* (1932).

The *Degrees* is Maritain's masterwork. He adopts Aquinas' distinction between philosophy and theology, whereby the latter is discourse whose principles are provided by divine revelation, and held by faith. One who does not hold the principles to be true will not hold as true the conclusions drawn from them. Theology, considered as a truth-seeking discipline, is thus an activity of believers. Philosophy, on the other hand, is discourse which proceeds from principles in the public domain, knowable by anyone; the philosopher must link his inferences to what everybody already knows.

This is obviously an Aristotelian view. Maritain sees Aquinas as an Aristotelian, and, accordingly, the Aristotelian division of philosophy into theoretical and speculative disciplines governs his thought. One of the interesting features of his work is the way he expands and reshapes that basic division to accommodate contemporary advances in thought.

Maritain's aim in the *Degrees* is to lay before us a vast and connected and hierarchical panorama so that we see our quest for knowledge as a graded ascent to wisdom *tout court*. He first discusses the relation between philosophy and experimental science, goes on to a plea for critical realism, discusses philosophical knowledge of sensible reality and then sets forth his metaphysics. The second part treats the relation between philosophy and mystical experience, and argues that the culmination of the human quest for truth is that wisdom which is a gift of the Holy Spirit. Like Aquinas, Maritain seeks a comprehensiveness which finds unity beyond necessary distinctions.

In 1931, thanks to a taunt by Émile Bréhier (in the *Revue de Métaphysique et de Morale*), a debate began on the nature of Christian philosophy. Was it possible for Christians to engage in philosophy or must their efforts be seen as the question-begging of believers? Maritain agreed that it would be nonsense to say that the Christian faith has no influence on the thinking of the believer. But the influence of faith has its analogue in the pre-philosophical assumptions of one ignorant of or hostile to the faith. Maritain distinguished between the act of philosophizing as a moral and human deed, and the product of such activity. With respect to the latter, believer and unbeliever, despite their differing existential starting points, must meet the same criteria for success. Maritain rejected the charge that Christian faith disqualifies one from philosophy; indeed, he considered it an aid and stimulus.

Few of Maritain's writings are exegetical, that is, close studies and interpretations of texts of Aquinas. Rather, having absorbed Aquinas, Maritain was interested in making him intelligible to modern philosophers, creating a new synthesis continuous with Aquinas' historical achievement. Étienne Gilson once wrote that he himself had spent his life seeking to know exactly what Aquinas meant, while Maritain was seeking to do in the present what Aquinas had done in the past.

3 Main arguments

Aesthetics. In 1920, Maritain published *Art and Scholasticism*, his second book. His wife was a poet, their friends were artists in various media - Rouault, Cocteau, Claudel, Péguy, Julien Green - and he felt a need to ask what the relation between art and philosophy is. The little book is a fascinating *mélange* of Aristotelian and Thomistic lore, but reveals as well Maritain's wide knowledge of literature and art. Many artists welcomed the Aristotelian truism that art aims at the perfection of the thing made, not of the maker. A salient mark of Maritain's aesthetics is his likening of poetic knowledge to the judgment of connaturality that Aquinas attributed to prudence. The Mellon Lectures, *Creative Intuition in Art and Poetry* (1953), bring to fruition Maritain's thoughts over many decades. They emphasize the knowledge which is prior to and may be expressed in artistic production.

Philosophy of science. For Aquinas, philosophy of nature establishes the possibility of a science beyond itself. If

natural change ultimately requires an uncaused cause, and thus one outside the realm of things that come to be (natural things), a science which treats of all being and not just natural beings suggests itself. Change involves matter; the changeless lacks matter, so to be and to be material are not identical. The development of modern science called into question the validity of Aristotelian physics, and this led some Thomists to seek to bypass it and begin with metaphysics. Maritain developed a distinction between experimental or empiriological (Maritain’s neologism) knowledge of nature and the philosophy of nature. The former, mathematical physics, falls short of knowledge of essence, the knowledge that characterizes philosophy of nature. This suggests that the matter/form analysis of sensible substance is ontological knowledge, profounder than the knowledge gained by the sciences. Developed in a number of books, Maritain’s position on this matter is also the first discussion in *The Degrees of Knowledge*.

Metaphysics. While Maritain’s position on metaphysics was initially similar to that of Aquinas, seeing the science of being as dependent for its very possibility on achievements in philosophy of nature, his approach changed, as is evident from *Existence and the Existent* (1947). There Maritain speaks of an intuition of being as the *sine qua non* of metaphysics. This intuition is not common to all, but is possessed only by a few. This development puts Maritain in the camp of those who feel that metaphysics can be undertaken without any prior science, philosophical or otherwise, of sensible reality. The ‘intuition of being’ seems to arise from the influence of existentialism. To some degree, it points to the need for a sense of wonder as the presupposition of philosophical questioning. Furthermore, it appears to be Maritain’s response to the interpretation of Gilson, who saw Aquinas’ use of *esse* as the key to his thought; the grasp of *esse* is part and parcel of the recognition that essence and existence are distinct, a recognition Gilson felt was missing from Aristotle.

Moral philosophy. It was in the area of moral philosophy that Maritain was most innovative. In Aquinas, we encounter the view that there are certain principles of action which are part of the natural repertoire of any human agent. Aristotle had articulated the ultimate end appropriate to the nature of the human agent, which end provides such limited happiness or fulfilment as is possible for humans. From the Christian point of view, Aristotle’s sense of the inadequacy of human happiness is just what is to be expected, since humans are destined for a higher happiness after their earthly existence. Aquinas thus spoke of imperfect and perfect beatitude, with ‘imperfect’ representing Aristotle’s own sense and not simply a Christian judgment. Maritain’s view is markedly different: he holds that no true conception of the ultimate end for humans is philosophically possible. Moral philosophy ‘adequately understood’ must be subordinated to moral theology, that is, must accept as true a conception of an ultimate end beyond our natural powers to discover. Critics accused Maritain of smudging the distinction between philosophy and theology and he was soon caught up in elaborate defences of his position (in, for example, *Science and Wisdom* (1935)).

Political philosophy. From involvement with the right-wing Action Française, condemned by the Catholic Church in 1926, Maritain moved leftward to the position of *Integral Humanism* (1936). Visits to the USA altered his critique of capitalism (see, for example, *Reflections on America* (1957)). The fall of France, and its wartime occupation, deeply affected him, and he became a champion of democracy and human rights. The role he played in the Universal Declaration on Human Rights of 1948 is evident in his Walgreen Lectures, which were published as *Man and the State* (1951). Here Maritain confronts the conflict between natural law and natural rights. He argues that the duties consequent on natural law and natural rights are two ends of the same thought.

A more timely problem arose from the fact that the signatories of the Universal Declaration held such radically different views of those rights. Maritain was incapable of a cynical explanation of this paradox, and he proposed a distinction between gnoseological and ontological natural law. Perhaps it would not simplify his point too much to say that the nature of the speakers and of the things spoken of in such situations provide an objective basis for agreement, whatever current misunderstandings obtain.

Theology. In the final phase of his career, Maritain’s writings became overtly theological, doubtless because they were occasioned by teaching the Little Brothers of Jesus in Toulouse. He and Raissa had written *Liturgy and Contemplation* in 1959, and in *The Degrees of Knowledge* he had ventured into mystical theology. *On the Grace and Humanity of Jesus* (1967) and *On the Church of Christ* (1970) and much of the posthumously published *Approches sans entraves* (1973) are purely theological. Among the surprises to be found in these late writings is a questioning of the eternity of the punishment of the damned even though they are forever incapable of the beatific

vision.

4 Influence

From the time of his conversion in 1906, Maritain regarded his Catholicism as the most essential thing in his life. The Christian vocation, the call to respond to grace and to the gifts of the Holy Spirit, was from the outset the frame within which his intellectual work was carried out. His understanding of the concept of Christian philosophy, as well as the constitution he wrote for the *Cercle d'Études Thomistes* (see his *Carnet de notes* (1965)), display his sense of the profound union of the intellectual and spiritual lives. Both Raissa and Jacques strove for holiness, and the testimony of friends suggests that their efforts were not unrewarded. They were instrumental in the return to the faith or conversion of many. The published correspondence between Maritain and Julien Green gives some flavour of what will be found in other, unpublished, letters.

Maritain's estimate of what was happening in the Church in the wake of Vatican II was not cheerful. *The Peasant of the Garonne* (1966) lamented the influence of Teilhard de Chardin and of phenomenology. He saw a resurgence of the modernism that had been condemned by Pius X in 1907. Some dismissed Maritain as out of date and grumpy.

As it happens, his influence continues and, indeed, increases. The Jacques Maritain Center at the University of Notre Dame, Indiana, was founded in 1948, and soon such centres sprang up around the world. There are two international Maritain societies and many national societies. A fifteen-volume *Oeuvres complètes* was completed in 1994, and a twenty-volume English edition began to appear in 1995.

Marius Victorinus (*fl.* 4th century AD)

Gaius Marius Victorinus was a rhetorician active in Rome in the fourth century AD. Classically educated and with an interest in philosophy, he converted to Christianity late in life and transferred his philosophical interests to Christian works. Strongly influenced by Neoplatonism, particularly by the works of Plotinus and Porphyry, he sought to articulate Christian concepts such as the Trinity in Neoplatonic terms. His writings on the Trinity and the soul influenced Augustine and other patristic philosophers.

Born in Africa some time in the decade AD 281-91, Victorinus acquired a classical education, including considerable knowledge of philosophy and its history. He wrote commentaries on the works of Cicero, produced treatises on grammar and logic and translated Greek philosophical works into Latin. Associated with aristocratic and senatorial circles, his success as a rhetor is evinced by the commissioning of a statue in his honour in the Forum of Trajan during his lifetime. In these activities, Victorinus represents a well-established Roman cultural type: the successful rhetorician with a learned interest in philosophy. Yet Victorinus was in the cultural vanguard of his time in one critical respect, his conversion to orthodox Christianity. We learn from St Jerome that this occurred 'in extreme old age', perhaps in the mid 350s. His late career was as an author of Christian theology, generating a series of commentaries on the letters of St Paul (Ephesians, Galatians, Philippians), as well as treatises of intra-Christian polemics. It is from these later theological works, directed primarily against the Arian heresy, and his translation efforts that Victorinus' subsequent philosophical reputation is derived.

Victorinus' interest in the philosophy of his time went well beyond the norm for a learned rhetorician. He translated some of Aristotle's logical works into Latin, as well as a large number of treatises from the *Enneads* of Plotinus and possibly some works of Porphyry, including the *Isagōgē*. This effort suggests both technical knowledge of philosophy and serious commitment to a cultural programme. His goal appears to have been the dissemination into the Latin world of contemporary Neoplatonism, particularly that of the Plotinian school (see Neoplatonism). Here Victorinus was successful not only among pagan readers, but also among his subsequent co-religionists, the Christians. These translations were essential to the assimilation of Plotinian and Porphyrian thought by Latin Christian intellectuals in the late fourth century (see Patristic philosophy). This fact is famously attested in Augustine's conversion narrative, the *Confessiones*; here, in Books VII-VIII, he describes the intellectual effect of reading - in the mid-380s - 'some books of the Platonists' (*Confessiones* VIII. 9.13) translated by Victorinus. These Neoplatonic treatises were decisive in motivating Augustine's acceptance of Christian monotheism, as they must have been at an earlier time for Victorinus himself (see Augustine).

Of Victorinus' philosophical ideas, we have only an imperfect record. His goal was to articulate the Christian Trinity in Neoplatonic terms, and to do so in a fashion that secured the orthodox conception of the consubstantiality of the Father and the Son. This theological desideratum was the source of his philosophical originality. In order to secure their monotheism, Christian thinkers were inclined either (a) to describe the Father, Son and Holy Spirit as modes or names of a single God, or (b) to treat the Son and Spirit as ontological derivatives of a primordial Father (see Trinity). The former, modalistic solution was articulated philosophically by Sabellius among others; the latter, subordinationistic approach was adopted by Origen of Alexandria, the Christian student of Plotinus' teacher Ammonius, and more forcefully by his later followers, including Victorinus' Arian opponents. Victorinus appears to have sought a way through this scholastic dichotomy by resorting to the subtle hypostatic theories of the Plotinian-Porphyrian school.

His approach was to treat the divine Father as a first principle defined in a fashion similar to the Plotinian One. The Father was above all being, beyond both the material things of the physical world and the Platonic intelligibles. In Victorinus' view, God, as the primordial Father, was best understood as 'pre-being' (*proon*), an absolute and perfect source for all finite reality. Beyond specification or determinate description, the Father was therefore beyond knowledge and the capacity of human conceptualization. As such, the Father makes his presence known through his Word or Son, the first being. The Son is the initial determination of the unlimited Father, the perfect manifestation of his hidden divine source. As the visible aspect of God, the Son is the 'form of God', the divine principle that brings out the latent nature of the Father. The Son thus gives finite form to the indefinite or formless substance of God the Father.

What is especially interesting about this Neoplatonic treatment of these Christian notions is Victorinus' recognition of the non-subordinationistic possibilities of Plotinian theology. He insists that the Father, as the unbounded source of all reality, cannot be juxtaposed as a distinct entity, superior in its own nature to that of the Son. Rather, the Father is the ontological ground of the Son, and as such, cannot be viewed either as external to the Son or as another being superior to him. If the Father is 'pre-being', then he is directly present to his first definite manifestation, his Word. Ontological subordination would seem therefore to be a misreading of what is not a hierarchical relation between separate entities. In Victorinus' model, the omnipresence of the Plotinian One thus becomes the basis for securing the consubstantiality of Father and Son, the hallmark of Nicene orthodoxy.

Victorinus is also noteworthy for his treatment of the human soul. The soul is brought into being by the creative activity of the Word, and bears its image: its capacity for rational reflection in particular reflects the order and structure of the Word. Within the soul, Victorinus discerned a triad of aspects indicative of its source in the divine: being, life and intellect. While fallen, the human soul retains this divine image, and has the capacity to restore its likeness to the Logos by exercising its intelligence and sloughing off the effects of its descent into time and change. In emphasizing the triadic structure of the descended soul and its isomorphism with the divine Trinity, Victorinus anticipated Augustine's subsequent interest in Trinitarian models of the soul and so the Western Christian articulation of the relation of the human and the divine (see Soul, nature and immortality of the).

Market, ethics of the

Markets are systems of exchange in which people with money or commodities to sell voluntarily trade these for other items which they prefer to have. Most economic transactions in advanced societies are of this kind, and any attempt to replace markets wholesale with a different form of economic coordination seems destined to fail. But questions about the ethics of markets are still of considerable practical concern, for two reasons at least. First, we need to make collective decisions about the proper scope of markets: are there goods and services which in principle should not be distributed and exchanged through market mechanisms - medical care, for instance? Second, markets work within a framework of property rights which sets the terms on which people can exchange with one another, and this too is subject to collective decision: for instance, should a person's labour be regarded as a commodity like any other, to be bought and sold on whatever terms the parties can agree, or does labour carry special rights that set limits to these terms? Are employees morally entitled to a share of the profits of the companies they work in, to take a concrete issue?

To guide such decisions, we need to apply general ethical principles to market transactions. First, are markets justified on grounds of efficiency, as is often claimed? What criterion of efficiency is being used when such claims are made? Second, can we regard the outcome of market exchanges as just, or, at the other extreme, should we see them as necessarily exploitative? Third, do market exchanges necessarily alienate people from one another and destroy their sense of community? These are very different questions, but an overall assessment of market ethics needs to address each of them, and perhaps others besides.

1 Efficiency

Informally, we describe institutions as efficient when they satisfy people's desires or preferences to the greatest possible extent. In this informal sense, it is easy to understand the efficiency claims made on behalf of markets. Viewed narrowly as a system of commodity exchange, a market enables people to exchange items they desire less for items they desire more, whereas whenever such exchanges are prevented, some people will have less of what they want than they might otherwise have. Viewed more broadly, as a mechanism for producing goods and services as well as exchanging them, a market provides incentives for people to make goods and provide services that other people want to buy. It also, as Hayek (1967) in particular has argued, economizes on information: individual people can make rational decisions about what and how much to produce on the basis of limited information about the costs and prices of a small number of goods and services, whereas a non-market system of production (such as a centrally-planned economy) would require some agency to assimilate data and coordinate behaviour across the whole economy (see Hayek, F.A. §2).

Economists have formalized the efficiency claim in the first theorem of welfare economics, which states that when a perfectly competitive market reaches equilibrium, this must be Pareto-optimal, meaning that no one's welfare can be further increased without reducing the welfare of someone else (see Economics and ethics §4; Pareto principle).

The efficiency claim is, however, subject to some large qualifications (for a fuller discussion, see Buchanan 1985). Real markets usually fall far short of the idealized markets of economic theory. Competition is imperfect - for instance rigidities are introduced when people invest in machinery or skills which cannot be easily redeployed when demand changes; individuals have been shown not to behave as rational maximizers of their utility; and, perhaps most importantly, many economic transactions generate positive or negative externalities such as spillover effects on third parties who have not consented to the exchange: Smith may open a new supermarket on the edge of town, and I and many others may voluntarily buy our groceries from him rather than from the corner store, but the effect is that the store has to close, imposing substantial costs on those who cannot easily travel to the supermarket; thus resulting in a negative externality. We cannot say therefore that real markets will be efficient, even by the Pareto criterion; there may be further resource transfers that such markets will not induce that would make everyone better off.

Next, Pareto optimality yields only a weak sense of efficiency. There are likely to be many resource allocations of which it is true that any reallocation will lower the welfare of at least one individual. The resource allocations generated by markets are characteristically quite unequal. By a stronger criterion of efficiency - for instance, a utilitarian criterion which tells us to aggregate welfare across individuals - efficiency would usually be increased

by redistribution from the better off to the worse off, at least up to the point where incentives begin to be affected (see Utilitarianism).

Finally, markets are said to be efficient in so far as they satisfy individuals' felt desires, which are expressed in their market behaviour - for instance, in their choice of consumer goods. This argument depends on interpreting individuals' welfare subjectively, in terms of existing preferences (see Welfare §1). If instead we were to measure welfare in terms of real interests or needs, then even the informal argument for market efficiency is put in question. Where markets meet desires that it is not genuinely to people's advantage to have satisfied, how can we advocate them on efficiency grounds?

In the light of these qualifications, the efficiency principle only provides a weak reason to favour markets; perhaps more importantly, it cannot adjudicate between economies in which almost everything is left to market mechanisms and economies where the state is more active in regulating the market and redistributing resources, such as social democracies (see Social democracy).

2 Justice and exploitation

Whether market outcomes are considered just or unjust depends on the theory of justice being applied (see Justice). At one extreme stands the view, associated particularly with Hayek, that the concept has no application to the results of a spontaneous process. Since no one intends to bring about the final outcome of a large set of market transactions, that outcome cannot be regarded either as just or as unjust. Against this, however, it has plausibly been argued that market outcomes are predictable, in their general shape if not their detail, and this is sufficient to bring the concept of social justice into play (Plant 1991).

Another view is that market transactions are always justice-preserving as long as they are fully voluntary - that is, neither side employs force or fraud to secure the transaction. This view appeals to a historical entitlement theory of justice of the kind favoured by Nozick and other libertarians (see Libertarianism; Nozick, R. §2). However, it is vulnerable to the problem of externalities that we have already encountered: a voluntary exchange between *A* and *B* may alter, perhaps for the worse, the position of *C*. Thus it seems that we have to look beyond individual transactions to consider the overall distribution of resources that results from the operation of market mechanisms over time.

Experience tells us that this distribution is likely to be quite unequal. Many philosophers would argue that such inequality is just in so far as it reflects the different choices that individuals may make - the choice to work rather than play, or to save rather than consume, for instance. Dworkin has developed a theory of this kind, where resources are initially to be divided equally among individuals, but where subsequent holdings may legitimately reflect such choices. On Dworkin's view, however, resource inequalities that stem from differences in native talent are unjust, and since much of the inequality in real-world markets appears to be of this kind, a just society would have to redistribute resources from the more talented to the less talented through a tax system.

This view can be challenged by invoking a stronger sense of desert, according to which people deserve the results of their productive efforts even when these depend on native abilities and dispositions that are not themselves deserved (see Desert and merit). Market outcomes could then be regarded as just in so far as they reflected the different productive achievements of individuals, as opposed to being the results of luck (Miller 1989). Such a justification will once again be vulnerable to the imperfections of real-world markets, where factors such as inherited advantage or monopoly power mean that many individuals will hold resources that by this criterion they do not deserve.

Philosophers in the socialist tradition have argued that many market transactions are exploitative. Notwithstanding their appearance of voluntariness, inequalities of resources or of bargaining power mean that one party is able to impose terms that make the exchange an unequal one. This applies particularly to labour contracts between workers and owners of capital. Marx developed the most celebrated theory of capitalist exploitation, arguing that an excess supply of labour would force workers to accept subsistence wages while their work created surplus value for their employers to appropriate (see Marx, K. §12). However, this theory relies on the one hand on a labour theory of value which now has few supporters, and on the other hand on a prediction about the future course of capitalism which has not been borne out.

More recent theories of economic exploitation have abandoned the labour theory of value, and have also attempted to widen the theory beyond the case of capital-labour exchanges. According to Roemer (1988), for instance, we can identify exploitation by asking whether there is a group of people who have to work for longer than is socially necessary to earn the bundle of goods they consume, and another group who need to work for less time. It emerges from these theories that although exploitation may emerge within markets, its source is always inequality in the assets or endowments that people bring to market exchanges. We can therefore enquire into the conditions under which markets can function without exploitation. This has led some political philosophers to develop theories of market socialism, examining the possibility of a market economy without private ownership of productive capital (Miller 1989; Schweickart 1993; Arnold 1994) (see Socialism §6).

3 Alienation and community

Even if markets can be framed in such a way that they are reasonably just and non-exploitative, they may still be criticized on the grounds that they set participants against one another and prevent them from enjoying fraternal or communal relations. Although market behaviour need not be motivated by narrow self-interest, it is in standard cases ‘non-tuistic’ (to use Wicksteed’s phrase), meaning that neither party to an exchange has any intrinsic concern for the welfare of the other. Each uses the other as an instrument for their own purposes, whatever these might be: when I buy oranges from the greengrocer, I have no interest in his wellbeing.

Marx once again gave fullest expression to this charge, when he described workers under capitalism as alienated, in part because they were prevented from enjoying those communal relations with their fellow workers which properly expressed their nature as human beings (see Marx, K. §4; Alienation §§3-5). But many others have attacked market societies for fomenting individualism and competition at the expense of social solidarity and community (see Community and communitarianism §3).

In reply to this, defenders of the market point out that, where markets are working properly, self-interested (or non-tuistic) behaviour on the part of each individual may contribute to the welfare of everyone; as Adam Smith famously argued, each is led by an ‘invisible hand’ to promote the interest of society more effectively than when they attempt to promote it directly (Smith 1776). Thus there is no conflict between producing or exchanging with a view to one’s own advantage and contributing to the welfare of others.

This reply only partly answers the original charge, however, because the existence of a community depends not just on how people act but on their intentions. We cannot describe the relationships that exist between buyers and sellers in a market as inherently communal. Yet there is no reason why communal relations should not develop alongside those of market exchange, for instance in workplaces, local communities or political associations. A society might then have a communitarian character overall, even though its economy was predominantly market-based.

What seems certain is that a world in which people interacted with one another solely through market transactions would be not only morally barren, but probably unsustainable. The question that arises is how to prevent the market from encroaching upon spheres of social life that presently act as a counterbalance to it. Recently philosophers have begun to investigate the reasons why certain goods and certain human relationships need to be kept insulated from market mechanisms: for instance, why body parts should not be bought and sold, or why marriage should not be turned purely into a negotiated contract between husband and wife (Anderson 1993; Andre 1995; Walzer 1983). The reasons are quite varied, but one concerns the way exposure to market mechanisms may change the character of relationships for the worse, by, for instance, undermining trust: if I know that doctors stand to profit from the treatment they prescribe, will I have the same confidence in them as when they have no financial stake in the outcome?

A careful examination of the ethics of markets is likely to lead neither to an unqualified endorsement nor an unqualified rejection of market mechanisms. Instead it will encourage us to ask questions about the institutional framework of the market. How can we ensure that it remains competitive, and therefore efficient? Can we guarantee that each participant has access to sufficient resources that they will not be exploited? How do we prevent markets from encroaching into spheres of human life where they have no place?

Marsilius of Inghen (1330-96)

The theological and philosophical works of Marsilius of Inghen are characterized by a logico-semantical approach in which he followed John Buridan, combined with an eclectic use of older theories, often dating from the thirteenth century. These were sometimes more Aristotelian and sometimes more Neoplatonist. The label 'Ockhamist', which is often applied to Marsilius, has therefore limited value. He was influential on Central European philosophy of later centuries, both through his own philosophy and by the way he stimulated reform of university programmes. In the sixteenth century there were still references to a 'Marsilian way' in logic and physics.

1 Logic

The semantic approach is pivotal in Marsilius' philosophy. In his theory on the properties of terms, *suppositio* is the acceptance of a term in a proposition for the thing(s) concerning which the term is verified by way of the copula of the proposition. For example, in the proposition 'a man is running', the term 'man' supposits for any man that exists, because concerning any of them it may be verified through the copula. The definition of supposition is in line with William of Ockham and, more strictly, with Buridan, but Marsilius' semantics has distinctive characteristics. Unlike Buridan, he accepts 'something imagined' as the significate of a fictional term such as *chimera*. Moreover, Marsilius does not adopt 'natural supposition', which in his view is a kind of atemporal signification, for example, of 'man' and 'animal' in 'man is an animal'. In his *Logic*, John Dorp (*fl.* 1400) follows Buridan in all respects except for the chapter on supposition, in which Marsilius is his model.

A commentary on Alexander of Villadei's *Doctrinale* is ascribed to Marsilius, probably correctly. In this work, he presents a 'conceptualistic grammar'; congruency in language is not relegated to the level of spoken thought (as it was by Ockham and Aurifaber), but is a property primarily of mental language. The result is that the grammar of mental language, on which spoken language is dependent, is a 'speculative science' (see Language, medieval theories of).

2 Theory of science

Both Marsilius and Buridan differ from Ockham in accepting a broader view of the formal object of a science. Whereas Ockham is more nominalistic (according to him the immediate formal object is a mental proposition), Buridan and Marsilius also accept a 'remote object' (the term) and a 'most remote object' (the thing) as significates. When trying to determine the formal object of theology, Marsilius agrees with Thomas Aquinas that a science has one single formal object, which Marsilius defines for theology as 'God as goal of man'. This formal object is in fact a predicate, which supposits for God (Marsilius' semantic approach again), and to which all other objects are related. Any other science has a formal object analogous to theology, such as syllogism in the case of logic.

3 Natural philosophy

The concept of impetus received much attention in the history of medieval physics. According to Marsilius, a projectile when thrown moves forward not because it was pushed by the air (which in its turn was moved by the thrower), which is faster than the natural downward movement of the thing thrown (this was Aristotle's opinion). Instead, the action of the thrower gives the projectile a kind of property (the 'impetus') that causes the movement and diminishes on its own. Here Marsilius follows Buridan in certain respects, rather than Ockham.

In the medieval commentaries on Aristotle's *On the Heavens* the problem of the spot on the moon occupied a prominent place. Theories about the origin of the spot had to reckon with the generally accepted theory of the simple nature of the heavenly bodies. According to Marsilius and other fourteenth-century Parisian philosophers, the moon is one of the ethereal planets (it was not earthlike, as Albert the Great thought). They denied that the moon's spot originated from outside (as Thomas Aquinas maintained). In a simple body like the moon, density and rarity follow primarily from the essence, Marsilius says, while the spot follows from it in a secondary sense, because the essence is dependent on the causality of the sun. In their different ways, these philosophers blurred the Aristotelian demarcation between heavenly bodies and the sublunary region (see Natural philosophy, medieval).

Marsilius also deals with two problems on the borderline between physics and theology. He holds that from the viewpoint of natural philosophy, there cannot be a plurality of worlds separate from each other. From the viewpoint of faith, however, God can create more worlds, in which natural kinds may differ from those in our world. Here Marsilius' view differs from that of most thirteenth-century philosophers. Marsilius believes that the world could not possibly be eternal, and in this he dissents from, for example Thomas Aquinas and Thomas of Strasbourg, who held that God's power to create an eternal world did not detract from his perfection and his own eternity (see Eternity of the world, medieval views of).

Marsilius of Padua (1275/80-1342/3)

*Marsilius of Padua's Defensor pacis (Defender of Peace), written in 1324, is the most revolutionary political treatise of the later Middle Ages. Discourse One of the Defensor pacis can plausibly be read as a complete theory of the secular state. In a much longer second discourse, Marsilius attacks papal and priestly political power, which, especially in the claims to 'fullness of power' (*plenitudo potestatis*) sometimes made for the papacy, he presents as a major threat to civic tranquillity. The distinctive features of Marsilian theory are (a) its emphasis on broad participation in the legislative process as a guarantee of sound law, and (b) its insistence that supreme coercive power in any community must be held by a single, secular, popularly authorized 'ruling part' (*pars principans*).*

1 Life

Marsilius was born Marsilio dei Mainardini, son of a notary to the University of Padua. He lectured on natural philosophy and engaged in medical research and practice in Paris, where he was rector of the University in 1313. In 1326, when his authorship of the *Defensor pacis (Defender of Peace)* was discovered, he fled to the court of Ludwig of Bavaria, then at odds with the papacy over the need for papal approval of his election as emperor several years earlier. Marsilius defended Ludwig's authority as Roman emperor in the tract *De translatione imperii* (On the Transfer of the Empire), presumably written in 1326-7, through advice and action during Ludwig's Italian campaign of 1327-30, and in the *Defensor minor*, written by 1342. Marsilius was dead by April 1343.

2 The 'state' and its peace

The discussions of popular assemblies and civic affairs in Discourse One of the *Defensor pacis* are most easily understood in relation to the first of the two milieux in which Marsilius passed his political life, the northern Italian commune. From the beginning, however, Marsilius sought to construct a theory which could be used to resist papalist claims to power on any scale. Accordingly, the formal unit of his analysis is the *regnum*, which he defines, peculiarly, as 'something common to every species of temperate regime, whether in a single city or many' (*Defensor pacis* 1.2.2). The generic character of this definition, the dedication of the *Defensor pacis* to Ludwig of Bavaria, the Empire's history as a particular object of papal jurisdictional claims and the context of Marsilius' later life and writings give some support to an imperialist as well as a republican interpretation of his thought.

At any level, the aim of political association, according to Marsilius, is 'the sufficient life'. His exegesis of this Aristotelian concept is a comparatively modest one. Although he notes that those who live a civil life have leisure for the activities of the moral and intellectual virtues, the 'living well' of Aristotelian politics, Marsilius is less concerned than most medieval authors (for example, Thomas Aquinas) with orienting politics toward the perfect natural or supernatural fulfilment of human nature. He is more concerned with the factors producing or impeding the peaceful resolution of disputes and the cooperative functioning of those parts of a community which are devoted to meeting basic earthly needs. Thus, while he follows Aristotle (§27) in including the priesthood as one of the parts of a *regnum* (along with farmers, artisans, merchants and the like), he treats it as a part established and controlled by lay authority.

3 Legislation and government

The modest aim or final cause of Marsilian politics dictates an inclusive view of the parties qualified to participate as efficient causes in achieving that aim. To be sure, Marsilius is not a pure majoritarian. When he argues that the primary and proper efficient cause of the law is 'the people or the whole body of citizens, or the weightier part thereof', he immediately explains that by the 'weightier part' (*pars valentior*) he means to take into consideration both 'the quantity and the quality of the persons in that community over which the law is made' (*Defensor pacis* 1.12.3). Even with this qualification, however, Marsilius' conception of legislative authority is exceptionally populist for the period in which he wrote.

Marsilius follows Aristotle and medieval tradition in arguing that the rule of law is necessary for achieving civic justice, the common benefit and political stability. He departs from tradition (how sharply is controversial) in making coercive enforceability, rather than rational content, the essence of law. Hence, although the wisdom of

experts may be called on to formulate proposed legislation, it is the people's consent that gives these proposals the force of law. Citizen participation in the legislative process is important for Marsilius even on the score of knowledge, for he holds that the people can discern what is for their mutual benefit and are thus able to assess and improve the counsels of the wise few.

Popular authorization is also required for the establishment (and, if necessary, correction) of a government to enforce the law. Although Marsilius argued for elective monarchy as generally the best form of government, he left the choice of administration by one, few or many rulers to the people. Whatever its internal makeup, however, it is vital that the supreme government of a city or larger community operate as a numerical unity in relation to local jurisdictions (if any) and in establishing and regulating the other parts of the state mentioned above. If there were a plurality of governments, not reduced or ordered under one as supreme, 'the judgement, command and execution of matters of benefit and justice would fail, and because men's injuries would therefore be unavenged the result would be fighting, separation, and finally the destruction of the city or *regnum*' (*Defensor pacis* 1.17.3). Marsilius compared the cooperative functioning of the various parts of a temperate political community to the functioning of a healthy, well-ordered animal, in which 'the primary principle which commands it and moves it from place to place is one' (*Defensor pacis* 1.17.8). It is by impeding the operation of government, the political primary moving principle, that papal and other ecclesiastical interventions in civic affairs are inimical to peace.

4 Religion

Marsilius' insistence that all coercive power be concentrated in a popularly controlled unitary secular government was rightly seen as an attack on the characteristic legal dualism of medieval society, in which church courts had jurisdiction over clerics in all matters and over lay people in some, while civil courts had jurisdiction over the laity in the matters that remained. In Discourse Two of the *Defensor pacis*, Marsilius defended his own position as the authentically Christian one. He argued that, in contrast with recent popes, Christ and the apostles were not a threat to secular peace. While teaching what must be believed and done to attain blessedness in the future life, they acknowledged the authority of emperors and other secular rulers in this life. In this part of his argument, Marsilius incorporated contemporary Franciscan contentions that poverty and lack of political power were appropriate for those who wished to follow Christ most closely. However, the leading Franciscan thinker of the day, William of Ockham, sharply criticized some of Marsilius' own theses (for example, that Peter had no authority over the other apostles and that final authority for determining Christian doctrine rests with a general council). Marsilius' views on the relations between clerical and lay authority were influential in the sixteenth-century Protestant Reformation. His conception of popular participation as the source of all law and of all governmental authority has been seen as an anticipation of, if not a traceable influence on, Rousseau.

Marston, Roger (*c*.1235-*c*.1303)

Roger Marston, an English Franciscan philosopher-theologian, was a pupil of John Pecham and a fellow student with Matthew of Aquasparta. Following closely in the footsteps of his master, Marston championed the views of Augustine in a conscious effort to counteract the growing fascination with Averroistic Aristotelianism. Of his works, three sets of Quaestiones disputatae (Disputed Questions) and four sets of quodlibetal questions, the Quodlibeta Quatuor (Four Quodlibets), survive.

Marston was born in England in the second quarter of the thirteenth century. As a Franciscan friar, he studied in Paris during the late 1260s and early 1270s, where he most likely heard the *collationes* of Bonaventure. He was a pupil of John Pecham during the latter's Paris regency (1270-1) and a fellow student with Matthew of Aquasparta. Upon returning to England and receiving the magisterium, he taught at Cambridge and Oxford between *circa* 1276 and 1284. He served as minister provincial of the English Franciscans from 1292 to 1298, when he was most instrumental in promoting the academic career of Duns Scotus. He died around 1303 and was buried at Norwich. Of Marston's works, while his commentary on the *Sentences* of Peter Lombard appears to have been lost, three sets of *Quaestiones disputatae (Disputed Questions)* - On Eternal Emanation, On the State of Fallen Nature and On the Soul - as well as four sets of quodlibetal questions, the *Quodlibeta Quatuor*, have survived.

Following closely in the footsteps of his master, John Pecham, Marston championed the views of Augustine in a conscious effort to counteract the growing Averroistic Aristotelianism (see Augustinianism; Averroism). In response to the charge of arch-conservatism, he remarked that he did not cling to tradition out of mere habit but, after a reasonable scrutiny of the evidence, formed opinions that harmonized the writings of the saints with the wisdom of the philosophers. Marston must have felt his views vindicated by the 219 propositions condemned by Etienne Tempier in 1277, since he refers to these 'articles' occasionally in his *Quaestiones disputatae* (see Aristotelianism, medieval).

Marston showed some interest in metaphysics, dismissing, for example, any real distinction between essence and existence. His concern with logic was predominantly with its application to other sciences. He was aware of the *ars obligatoria* (*Quodlibet* IV q.5: 375; *Quaestiones disputatae de anima* q.10: 453) (see Logic, medieval). Apart from purely theological questions and matters of canon law, his philosophical thinking focused on epistemology, natural philosophy and psychology (as understood in medieval times).

Regarding epistemology, Marston maintained that the material elements of cognition - for example, grasping the terms of a proposition - come from sense knowledge or the imagination and reside in the intellectual memory. The formal elements, however - in other words, the infallible and immutable evidence for the truth - come from what Augustine called the 'eternal reasons' or divine illumination. Like Roger Bacon, Marston claimed that this was the same as the agent intellect of Aristotle and Averroes (see Ibn Rushd), although in opposition to Averroes, he claimed that there was no single agent intellect for all mankind, but that each individual had his own. Marston claimed that 'species' - for example, 'images' or 'idols' remaining after sensation or intellection - were necessary for knowledge. Like Pecham and unlike Duns Scotus, Marston claims a direct intellectual knowledge of singulars.

In the realm of natural philosophy, Marston insists (contrary to Aquinas) that matter has its own essence and positive nature apart from any form. Marston is likewise an indefatigable defender of the plurality of grades of the form theory (*Quodlibet* II q.22: 232-78), in opposition to the 'uniformism' of Aquinas and the 'dimorphism' of Henry of Ghent. The vegetative and sensitive functions (grades of the form) are not supplanted by the infusion of the rational soul, as Aquinas held, but they persist as grades of the rational soul considered as the form of the human being (see Natural philosophy, medieval).

Like his teacher Pecham, Marston advanced 'proofs' for the immortality of the soul. In much the same fashion as his protégé Duns Scotus, Roger strongly defended the freedom of the will to the degree that choice could be exercised not simply regarding means to the final end, but even with regard to man's final goal as well. In the footsteps of Bonaventure and Pecham, Marston rejected even the possibility of a created world eternally coexistent with the creator.

Roger Marston is noteworthy for the clarity and well-organized presentation of his views. He is likewise an

invaluable witness to the doctrinal disputes prevalent at his time.

Martineau, Harriet (1802-76)

Harriet Martineau has been called the first woman sociologist and the first woman journalist in England, both better claims on the attention of posterity than her mostly derivative philosophical writings. Yet she is a revealing - and was in her own time widely influential - instance of the survival of eighteenth-century determinism and materialism. Although she eventually rejected the Unitarianism in which she had been brought up, the Necessarian philosophy she drew from it merged easily into her mature positivism. Her abridged translation (1853) of theCours de philosophie positive was the first introduction of this seminal work byAuguste Comte to English-speaking readers.

Harriet Martineau was born in Norwich on 12 June 1802. As a child, she suffered ill health and more than the usual fears and loneliness; by the age of 20 she was almost totally deaf. Her excellent, if formally haphazard, early education was extended by carefully planned reading, with strong encouragement from a family solidly established among the liberal Unitarians in Norwich and elsewhere.

Devotional and religious themes marked her early writing - mostly in the Unitarian *Monthly Repository* - but she turned increasingly to philosophical issues. Entirely dependent on her pen after the death of her father, a textile manufacturer, in 1826, and the failure of the family firm three years later, in 1832 she launched *Illustrations of Political Economy*, a monthly series of 23 tales which caught, as she did so often, a new enthusiasm at its height, bringing her a celebrity she never lost. On completion of the tales, she spent the years 1834-6 in the USA. *Society in America* (1837), the first of two accounts of her travels, shows formidable powers of observation and synthesis and contains much original sociological comment, while in *How to Observe: Morals and Manners* (1838), she set out general principles for social analysis. *Deerbrook* (1839), her only large-scale novel, offered a characteristically sympathetic portrayal of middle-class life and enforced the subordination of passion to duty and service to others. Extraordinarily generous with her own modest income, she advocated many causes, among them anti-slavery, education, and the legal, political and economic liberation of women. Her radicalism broadened as she grew older and the stringency of her early political economy lessened.

Stricken in 1840 by debilitating symptoms resulting from an ovarian cyst, she retreated to Tynemouth, where her writing continued apace and her thinking matured, with some oddly self-absorbed turns. In 1845, she pronounced herself cured by mesmerism and resumed an active life, eventually settling in the Lake District. An extended tour of the Near East, recorded in *Eastern Life, Present and Past* (1848), further distanced her from religion, and *Letters on the Laws of Man's Nature and Development*, written with Henry George Atkinson in 1851, proclaimed her loss of conventional belief. A brilliant, opinionated critic, a gifted contemporary historian and a keen observer of politics and international affairs, in 1852 she began to write regularly for the London *Daily News*, contributing more than 1,600 leading articles before her retirement in 1866. She died in Ambleside on 10 April 1876.

Harriet Martineau was no mere popularizer. Rather, insistent on candid 'publication of opinion' and determined to instruct the nation, she gathered together many of the major intellectual strands of her time, forcing them into broad public awareness at crucial moments.

Like most serious-minded English Unitarians of her generation, she was persuaded by Necessarianism, a deterministic philosophy derived from the psychological and religious speculations of David Hartley (§2), the systematizer of associationism, and transmitted through the scientist and theologian Joseph Priestley, from whom she also drew her materialism. Convinced that free will is an illusion, Necessarians distinguished their views from fatalism or Calvinist predestinarianism by insisting on the malleability of motives which, built up through association, inescapably determined all human actions. Education and personal influence could thus bring everyone to think rightly, to understand the laws of nature and even to attain perfection. This optimism and certainty survived her firm, unfairly scornful rejection of the Unitarianism that had engendered it.

Open to a wide range of current discussion, she added her own observations and experience, including mesmeric phenomena, to create a scientistic synthesis in which Baconian faith in fact-based induction was conditioned by insistence on the importance of guiding, selective principle. As religion came to seem no more than a historically conditioned phenomenon, she turned to positivism, for which she had been prepared by the Saint-Simonian

missionaries who came to London from France in the early 1830s. In 1853, she published an abridged translation of Auguste Comte's *Cours de philosophie positive*, its first introduction to the English-speaking world. Although she rejected social hierarchy, the subordination of women and the quasi-religious turn ofComte's later work, she found in the centrality he gave to laws of thought and to scientific views of society the final distillation of her Necessarianism (see Comte, A.).

She had shared that early commitment with her younger brother James, a Unitarian minister who, from 1833, was in rebellion against Priestleyanism. Influenced by German theology and philosophy and by romanticism, he insisted that apprehension of religious truth was grounded in introspection rather than in revelation and evidences from nature. Their increasing alienation, culminating in his extremely hostile review of the Atkinson letters in the *Prospective Review*, made her a willing conspirator in the successful campaign in 1866 (led by the psychologist Alexander Bain) to deny him, as a minister, the chair of philosophy at the historically non-sectarian University College London, a post many thought a merited recognition of his periodical writings and his lectures at the Unitarian Manchester College. The lectures became books in the 1880s, too late to have the influence they might have commanded twenty years earlier.

The posthumous publication of her frank and judgmental autobiography inflicted considerable damage on her reputation, which, though she never lacked admirers, only began a real recovery in the 1960s, when historians, literary critics and feminists began to take proper measure of a career of astonishing energy and accomplishment.

Marx, Karl (1818-83)

Karl Marx was the most important of all theorists of socialism. He was not a professional philosopher, although he completed a doctorate in philosophy. His life was devoted to radical political activity, journalism and theoretical studies in history and political economy.

Marx was drawn towards politics by Romantic literature, and his earliest writings embody a conception of reality as subject to turbulent change and of human beings as realizing themselves in the struggle for freedom. His identification with these elements in Hegel's thought (and his contempt for what he regarded as Hegel's apologetic attitude towards the Prussian state) brought Marx to associate himself with the Young Hegelians.

The Young Hegelians had come to believe that the implicit message of Hegel's philosophy was a radical one: that Reason could and should exist within the world, in contrast to Hegel's explicit claim that embodied Reason already did exist. Moreover, they also rejected Hegel's idea that religion and philosophy go hand in hand: that religion represents the truths of philosophy in immediate form. On the contrary, the Young Hegelians saw the central task of philosophy as the critique of religion - the struggle (as Marx himself was to put it in his doctoral dissertation) 'against the gods of heaven and of earth who do not recognize man's self-consciousness as the highest divinity'.

Marx came to be dissatisfied with the assumption that the critique of religion alone would be sufficient to produce human emancipation. He worked out the consequences of this change of view in the years 1843 to 1845, the most intellectually fertile period of his entire career. Hegel's philosophy, Marx now argued, embodied two main kinds of mistake. It incorporated, first, the illusion that reality as a whole is an expression of the Idea, the absolute rational order governing reality. Against this, Marx's position (and on this point he still agreed with the Young Hegelians) was that it is Man, not the Idea, who is the true subject. Second, he charged, Hegel believed that the political state - the organs of law and government - had priority in determining the character of a society as a whole. In fact, according to Marx, this is the reverse of the truth: political life and the ideas associated with it are themselves determined by the character of economic life.

Marx claimed that the 'species-being' of Man consists in labour, and that Man is 'alienated' to the extent that labour is performed according to a division of labour that is dictated by the market. It is only when labour recovers its collective character that men will recognize themselves as what they are - the true creators of history. At this point, the need to represent the essence of human beings in terms of their relation to an alien being - be it the Christian God or Hegelian Geist *- will no longer exist.*

In the mature writings that followed his break with the Young Hegelians, Marx presented a would-be scientific theory of history as a progress through stages. At each stage, the form taken by a society is conditioned by the society's attained level of productivity and the requirements for its increase. In pre-socialist societies this entails the division of society into antagonistic classes. Classes are differentiated by what makes them able (or unable) to appropriate for themselves the surplus produced by social labour. In general, to the extent that a class can appropriate surplus without paying for it, it is said to be an 'exploiting' class; conversely, a class that produces more than it receives is said to be 'exploited'.

Although the exploiting classes have special access to the means of violence, exploitation is not generally a matter of the use of force. In capitalism, for example, exploitation flows from the way in which the means of production are owned privately and labour is bought and sold just like any other commodity. That such arrangements are accepted without the need for coercion reflects the fact that the ruling class exercises a special influence over ideas in society. It controls the ideology *accepted by the members of society in general.*

In Das Kapital (Capital), the work to which he devoted the latter part of his life, Marx set out to identify the 'laws of motion' of capitalism. The capitalist system is presented there as a self-reproducing whole, governed by an underlying law, the 'law of value'. But this law and its consequences are not only not immediately apparent to the agents who participate in capitalism, indeed they are actually concealed from them. Thus capitalism is a 'deceptive object', one in which there is a discrepancy between its 'essence' and its 'appearance'.

In Marx's view, it is inevitable that capitalism should give way to socialism. As capitalism develops, he believed,

the increasingly 'socialized' character of the productive process will conflict more and more with the private ownership of the means of production. Thus the transition to collective ownership will be natural and inevitable. But Marx nowhere explained how this collective ownership and social control was to be exercised. Indeed, he had remarkably little to say about the nature of this society to the struggle to which he devoted his life.

The Critique of the Gotha Programme envisaged two phases of communist society. In the first, production will be carried out on a non-exploitative basis: all who contribute to production will receive back the value of what they have contributed. But this, Marx recognized, is a form of 'equal right' that leaves the natural inequalities of human beings unchecked. It is a transitional phase, although inevitable. Beyond it there lies a society in which individuals are no longer 'slaves' to the division of labour, one in which labour has become 'not only a means of life but life's prime want'. Only then, Marx thought, 'can the narrow horizon of bourgeois right be crossed in its entirety and society inscribe on its banners: from each according to his ability, to each according to his needs!' This is the final vision of communism.

1 Life and works

Marx was born on 5 May, 1818, in Trier, a small, originally Roman city on the river Moselle. Many of Marx's ancestors were rabbis, but his father, Heinrich, a lawyer of liberal political views, converted from Judaism to Christianity and Marx was baptized with the rest of his family in 1824. At school, the young Marx excelled in literary subjects (a prescient schoolteacher comments, however, that his essays were 'marred by an exaggerated striving after unusual, picturesque expression'). In 1835, he entered the University of Bonn to study law. At the end of 1836, he transferred to Berlin and became a member of the Young Hegelian *Doktorklub*, a bohemian group whose leading figure was the theologian, Bruno Bauer. The views of the *Doktorklub* became increasingly radical (to some extent, it would seem, under Marx's influence) in the late 1830s.

Marx's father died in 1838 and in the next year - perhaps not coincidentally - Marx abandoned the law in favour of a doctorate in philosophy. His thesis, *Differenz der demokritischen und epikureischen Naturphilosophie (Difference between the Democritean and Epicurean Philosophy of Nature)* was accepted by the University of Jena in 1841. Marx had hoped to use it to gain an academic position, but, after Bruno Bauer's suspension from his post at the University of Bonn, it became apparent that such hopes would have to be abandoned in the current political climate.

Marx turned instead to journalism, involving himself with the newly-founded *Rheinische Zeitung* and taking over the editorship in October 1842. However, the paper came increasingly into conflict with the Prussian government and was banned in March 1843. At this point, Marx decided to move abroad. In the summer he married Jenny von Westphalen (after an engagement of six years) and during a long honeymoon in Kreuznach worked on *Zur Kritik der Hegelschen Rechtsphilosophie (Critique of Hegel's Philosophy of Right)* and the essay 'Zur Judenfrage' ('On the Jewish Question') in which he started to formulate his disagreements with his fellow Young Hegelians. He and Jenny moved to Paris in October of that year. It was in 1844 that Marx met up again with Friedrich Engels (whom he had known slightly in Berlin) and the alliance was formed that was to last for the rest of Marx's life. Together Marx and Engels wrote *Die Heilige Familie (The Holy Family)* (1845a), a polemic against Bruno Bauer. More important, however, was the body of writing on economics and philosophy that Marx produced at this time, generally known as *The Paris Manuscripts* (1844).

Marx was expelled from France in 1845 and moved to Brussels. In the spring of 1845, he wrote for his own clarification a series of essays on Feuerbach. These 'Theses on Feuerbach' are one of the few mature statements we have of his views on questions of epistemology and ontology. In 1845-6 Marx and Engels wrote *Die deutsche Ideologie (The German Ideology)* which, although it too remained unpublished, contains an authoritative account of their theory of history and in particular of the place of ideas in society. Marx's developing economic views were given expression in a polemic against Proudhon, *La Misère de la Philosophie (The Poverty of Philosophy)*, published in 1847.

Das Kommunistische Manifest (The Communist Manifesto), written by Marx and Engels as the manifesto of the Communist League in early 1848, is the classic presentation of the revolutionary implications of Marx's views on history, politics and economics. During the revolutionary upsurge of 1848 Marx returned to Germany, but with the defeat of the revolutionary movement he was forced to leave, first for Paris, and then, in August 1849, for London,

where he would live in exile for the rest of his life.

The years of exile in Britain were difficult ones for Marx (and even more so for his loyal and devoted family). He was in constant financial difficulty and had to rely heavily on Engels and other friends and relations for support. His theoretical activities were chiefly directed to the study of political economy and the analysis of the capitalist system in particular. They culminated in the publication of the first volume of *Das Kapital (Capital)* in 1867. However, *Das Kapital* is the tip of a substantial iceberg of less important publications and unpublished writings. Among the former, the Preface to *Zur Kritik der politischen Ökonomie (A Contribution to the Critique of Political Economy)* published in 1859, contains the classic statement of Marx's materialist theory of history. The second and third volumes of *Das Kapital*, left unfinished at Marx's death, were edited and published posthumously by Engels. In addition, three volumes of *Theorien über den Mehrwert (Theories of Surplus-Value)*, a series of critical discussions of other political economists, written in 1862-3, were published in the early twentieth century. An extensive and more or less complete work, the *Grundrisse der Kritik der politischen Ökonomie* (known both in English and in German as the *Grundrisse*) was written in 1857-8 but only published in 1939. The Introduction to the *Grundrisse* is the mature Marx's most extended discussion of the method of political economy. In addition, there exist numerous notebooks and preliminary drafts, many (if not, at the time of writing, all) of which have been published.

Political economy apart, Marx wrote three works on political events in France: *Die Klassenkämpfe in Frankreich (Class Struggles in France)* (1850), *Das achtzehnte Brumaire des Louis Bonaparte (The Eighteenth Brumaire of Louis Bonaparte)* (1852) and *The Civil War in France* (1871). Among his many polemical writings, the *Kritik des Gothaer Programms (Critique of the Gotha Programme)* (1875) is particularly important for the light it throws on Marx's conception of socialism and its relation to ideas of justice.

Marx was in very poor health for the last ten years of his life, which seems to have sapped his energies for large-scale theoretical work. However, his engagement with the practical details of revolutionary politics was unceasing. He died on 14 March 1883 and is buried in Highgate Cemetery, London.

2 Marx as a Young Hegelian

Marx is relevant to philosophy in three ways: (1) as a philosopher himself, (2) as a critic of philosophy, of its aspirations and self-understanding, and (3) by the philosophical implications of work that is, in Marx's own understanding of it, not philosophical at all. Broadly speaking, these three aspects correspond to the stages of Marx's own intellectual development. This and the following section are concerned with the first stage.

The Young Hegelians, with whom Marx was associated at the beginning of his career, did not set out to be critics of Hegel. That they rapidly became so has to do with the consequences they drew from certain tensions within Hegel's thought. Hegel's central claim is that both nature and society embody the rational order of *Geist* (Spirit). Nevertheless, the Young Hegelians believed, it did not follow that all societies express rationality to the fullest degree possible. This was the case in contemporary Germany. There was, in their view, a conflict between the essential rationality of *Geist* and the empirical institutions within which *Geist* had realized itself: Germany was 'behind the times' (see Hegel, G.W.F. §§5-8; Hegelianism §§2-3).

A second source of tension lay in Hegel's attitude towards religion. Hegel had been prepared to concede a role to religion as the expression of the content of philosophy in immediate form. The Young Hegelians, however, argued that the relationship between the truths of philosophy and religious 'representation' was, in fact, antagonistic. In presenting reality not as the embodiment of reason but as the expression of the will of a personal god the Christian religion establishes a metaphysical dualism that is quite contrary to the secular 'this-worldliness' which (although Hegel himself might have been too cautious to spell it out fully) is the true significance of Hegel's philosophy.

This was the position endorsed by Marx at the time of his doctoral dissertation on Epicurus and Democritus. Its subject was taken from a period of Greek thought that displayed parallels with the Germany of Marx's own time. Just as the Young Hegelians faced the problem of how to continue philosophy after Hegel, so Epicurus wrote in the shadow of another great system, that of Aristotle. Epicurus is more successful than Democritus, Marx believes, in combining materialism with an account of human agency. Furthermore, Marx admires Epicurus for his explicit critique of religion, the chief task of philosophy, he asserts, in all ages.

In its destruction of the illusions of religion, the Young Hegelians believed that philosophy would provide both the necessary and the sufficient conditions for human emancipation and the achievement of a rational state. In the works that he wrote in Kreuznach in 1843 (the unpublished draft of the *Critique of Hegel's Philosophy of Right* and the essay 'On the Jewish Question') and shortly thereafter (the '*Critique of Hegel's Philosophy of Right*: Introduction') Marx called this position into question.

In the *Critique of Hegel's Philosophy of Right* Marx makes two main criticisms of Hegel. The first is that Hegel's real concern is to retrace in the political realm the outlines of his own metaphysics, rather than to develop an analysis of political institutions and structures in their own right. This gives his political philosophy an apologetic function, for it leads him to present the contradictions that he finds in reality as essentially reconciled in the supposedly higher unity of the 'Idea'. But they are not, says Marx. On the contrary, they are 'essential contradictions'.

Chief among such contradictions is that existing between the 'system of particular interest' (the family and civil society - that is, economic life) and the 'system of general interest', namely, the state. And this leads to Marx's second criticism. Hegel, Marx alleges, assumes that the state, because it is 'higher' from the point of view of Hegelian logic, can effectively reconcile the contradictions of economic life. In fact, in Marx's view, it is civil society that exists prior to the state. The state arises from the condition of civil society and is always subordinate to the form of the latter.

3 Philosophy and the critique of religion

Marx presents the implications of these criticisms for the critique of religion in the *Critique of Hegel's Philosophy of Right*: 'Introduction'. This short essay is a compressed masterpiece of vehement rhetoric, seething with antithesis and chiasmus. In Germany, Marx writes, 'the critique of religion is essentially completed'. Thus the problem is how to go beyond it. Marx's first step is to explain the significance of that critique, as he understands it.

The world of religion is a reflection of a particular form of society: 'This state, this society, produce religion, which is an inverted world-consciousness, because they are an inverted world'. That is to say, only an inverted, secular world would produce religion as its offshoot. In religious belief, Man finds himself reflected in the 'fantastic reality of heaven', whilst he can find only 'the semblance of himself, only a nonhuman being' in this world. Religion thus provides a realm in which individuals can realize themselves, at least partially, given that full and adequate self-realization is not possible in the profane world. In this way, religion preserves the social order of which it is a by-product, both by deflecting attention from its defects and by providing a partial escape from it. In Marx's famous words, 'Religion is the sigh of the oppressed creature, the heart of a heartless world and the soul of soulless conditions. It is the opium of the people'.

Thus religion and the form of life associated with it are open to criticism at three points. (1) There is, first, the impoverished and distorted world of which religion is a by-product. (2) There is the way in which the image of reality produced by religion is falsely transfigured. (3) Finally, there is the failure by human beings to recognize the fact that religion has its origins in mundane reality.

It is this last element towards which the critique of religion is directed. Critique of religion connects religion back to its unacknowledged origins in social existence. Yet this is not enough. The critique of religion, inasmuch as it is a call to people to abandon their illusions, is also, according to Marx, 'the call to abandon a condition that requires illusions'. By itself the critique of religion cannot remove the distortion and impoverishment of the world from which religion arises. This is of course Marx's real project, for which the criticism of religion has merely prepared the ground.

Once the criticism of religion has done its work, philosophy must move on 'to unmask human self-alienation in its secular forms'. The critique of religion ends, Marx says, 'in the doctrine that man is the supreme being for man; thus it ends with the categorical imperative to overthrow all conditions in which man is a debased, enslaved, neglected, contemptible being' (1843a: 251).

Much of this analysis represents common ground between Marx and his Young Hegelian former associates. Marx concedes that philosophy has both a critical role to play in exposing the illusions of religion and an affirmative one

in establishing an ideal of human fulfilment. Nevertheless, Marx takes the Young Hegelians to task for thinking that philosophy alone provides a sufficient condition for human emancipation. Philosophy, he maintains, must move beyond itself: ‘criticism of the speculative philosophy of right does not remain within itself, but proceeds on to tasks for whose solution there is only one means - praxis’. For this, a material force - a ‘class with radical chains’ - is required, namely, the proletariat.

At this stage, then, Marx is critical not so much of the content of philosophy, but of what we might call the metaphilosophical belief associated with it: that it is possible (as he puts it in relation to the Young Hegelians) ‘to realize philosophy without transcending it’. A truly successful critique of religion would require the transformation of the social conditions within which religion is generated and sustained.

4 Alienated labour

In Paris, Marx threw himself into the study of political economy. His objective was to amplify his critique of Hegel and the Young Hegelians with a more far-reaching account of the nature of ‘civil society’. The *Paris Manuscripts* thus provide a unique link between Marx’s economic theory and his philosophical view of human nature. The concept which brings the two together is that of alienation (*Entfremdung*) (see Alienation §§3-5). Although Marx had made little use of this term in his earlier writings, the structure of the concept is clearly anticipated in his critique of religion. The fundamental idea is that an entity or agent gives rise to a product or expression that is distinct from but at the same time essential to itself. This secondary product comes to be cut off from its origin. In consequence, the agent suffers a loss of identity in some sense. Thus, for the agent to realize itself fully, it must remove the separation that has come between itself and its own product.

In the central discussion of the *Paris Manuscripts*, Marx sets out to apply the concept of alienation to the labour process. Alienation, Marx argues, is characteristic of a situation in which (1) labour is directed towards the production of commodities (that is, goods exchangeable in the market) and (2) labour itself is such a commodity. Marx divides the alienation involved in labour into three main forms.

(1) There is, first, the separation of the worker from the product of labour. It is in the nature of the labour process that it involves ‘appropriating’ the external world. But when labour is alienated, the sensible, external world becomes an object to which the worker is bound, something that is hostile to them, instead of being the means to their self-realization.

(2) At the same time, the labour process itself becomes alien to the worker. Because the imperatives according to which labour takes place come to the worker ‘from outside’ (that is, from the market, either directly or indirectly) labour is no longer an act of self-realization. It becomes, from the worker’s point of view, ‘an activity directed against himself, which is independent of him and does not belong to him’.

(3) Finally, Marx says, the consequence of these two forms of alienation is to alienate man from what he calls his ‘species-being’ (*Gattungswesen*). The latter concept (of which Marx made frequent use in 1843-4) is adapted from Ludwig Feuerbach. Man, says Marx, is a species-being ‘because he looks upon himself as the present, living species, because he looks upon himself as a *universal* and therefore free being’.

An analogy that may help to clarify this apparently circular definition can be made with the family. In a limited sense, people can be part of a family without consciously behaving accordingly (at the limit, we can think of members of a family who do not even know that they are related). But in order to be a family in a fuller sense, people must relate to one another *as* a family, and at least a part of this is that they should be aware that they *are* a family. So it is with human species-being. While the fundamental phenomenon on which the family is based is a biological relation, in human species-being it is labour. Thus, as labour is alienated in other respects, so people become alienated from their species-being. The consequence is the alienation of members of the species from one another.

Each of these three points is, one might think, somewhat questionable. Surely, in any situation in which individuals do not produce entirely for themselves, it will be inevitable that the products of labour are ‘separated’ from the original producer. Likewise, the labour process cannot be something that is freely chosen by individuals as long as they are objectively constrained by the nature of the material world and the resources available to them in finding efficient means to given ends. Finally, it is not at all clear what is involved in human

beings ‘re-appropriating’ their ‘species-being’.

One way of making the concept of alienated labour more precise is to ask what it might be for labour to be non-alienated. Marx addresses the issue at the end of a discussion of James Mill’s *Elements of Political Economy*. ‘Let us suppose’, Marx begins, ‘that we had produced as human beings’. In that case, he claims, each of us would have ‘affirmed’ both ourselves and our fellows in the process of production. In the first place, I, the producer, would have affirmed myself in my production. At the same time, I would be gratifying a human need - that of my neighbour, for whom I am in this case producing. Thus, in meeting your need, I would have mediated between you and the species: ‘I would be acknowledged by you as the complement of your own being, as an essential part of yourself’. In this way, production and the meeting of needs involves a mutuality of self-realization and reciprocal recognition:

> In the individual expression of my own life I would have brought about the expression of your life, and so in my individual activity I would have directly *confirmed* and *realized* my authentic nature, my *human*, *communal* nature.
>
> (1844: 277-8)

These ideas help to explain Marx’s antagonism towards what he would call ‘bourgeois’ political theory. In so far as traditional political philosophy takes as its fundamental question how to reconcile competing interests, its starting point is, from Marx’s point of view, unacceptably individualistic. For what entitles us to assume that the interests of individuals are bound to be antagonistic? Rather than asking how to allocate rights and duties fairly when interests conflict, the task, Marx believes, is to move humanity towards a form of life in which conflicts of interest are no longer endemic.

5 The critique of philosophy

Although the *Paris Manuscripts* show Marx’s increasing engagement with political economy, they do not represent an abandonment of his concern with philosophy. The attitude that Marx takes towards philosophy, however, now becomes more critical than it had been in his earlier, Young Hegelian period. In part, this can be traced to Ludwig Feuerbach, whom Marx quotes approvingly at several points (see Feuerbach, L. §2). It was Feuerbach’s great achievement, Marx writes, ‘to have shown that philosophy is nothing more than religion brought into thought and developed in thought, and that it is equally to be condemned as another form and mode of existence of the alienation of human nature’. Thus Marx now regards philosophy as essentially continuous with religion, not a force directed against religion, as he had represented it at the time of his doctoral dissertation.

Marx makes a number of negative remarks regarding philosophy in general, but his more specific critical comments are directed towards Hegel. Like Feuerbach, he takes the view that Hegel has brought philosophy to a point of completion. The dynamic principle at the heart of Hegel’s philosophy, according to Marx, is that of ‘abstract mental labour’. Nevertheless, despite the genuinely critical elements contained within it, Hegel’s philosophy is vitiated by its idealist assumptions. In the end, for Hegel, alienation is merely a matter of the separation of the products of thought from thought itself, something to be overcome by a philosophical reorientation of consciousness. To go beyond Hegel, it would be necessary to make the concept of real, concrete labour fundamental. But this, Marx suggests, leads beyond philosophy itself.

Marx pursues these ideas in the ‘Theses on Feuerbach’, written in the spring of 1845. Here he makes it explicit that his disagreement is not only with idealistic philosophies, such as Hegel’s, but also with would-be materialist ones, Feuerbach’s included. In incorporating within itself an idea of ‘activity’, idealism has important advantages over materialism. It is, Marx writes,

> the chief defect of all hitherto existing materialism (that of Feuerbach included)…that the thing, reality, sensuousness, is conceived only in the form of the object or of contemplation, but not as sensuous human activity, praxis, not subjectively. Hence, in contradistinction to materialism, the *active* side was developed abstractly by idealism - which, of course, does not know real sensuous activity as such.
>
> (1845b: 421)

It should be noted that this passage is ambiguous. Is Marx envisaging a new kind of materialism (one that would not have the defects of ‘hitherto existing materialism’) or is it a call to leave philosophy - both materialism and

idealism - behind altogether? Interpreters of Marx who take the former view have ascribed an implicit philosophical position to him (often called ‘dialectical materialism’). Nevertheless, the fact remains that Marx himself never developed such a position explicitly, and the conclusion of the ‘Theses on Feuerbach’ appears to lead away from philosophy entirely: ‘The philosophers have only *interpreted* the world in various ways; the point is to *change* it.’

The German Ideology, which Marx and Engels wrote from September 1845 to the summer of 1846, continues this line of argument. As in so many of Marx’s writings, the rhetorical trope from which the criticism starts is that of an inversion of an inversion. The Young Hegelians, Marx alleges, think of themselves as engaged in a struggle with the illusions that hold the Germans in their grip. But in fact they are in the grip of an illusion themselves: the illusion that ideas are an independent, determining force in political life. Feuerbach is not excepted from this criticism. Although he purports to demystify the realm of pure ideas, he still remains, according to Marx and Engels, ‘in the realm of theory’. Feuerbach, they claim, ‘never arrives at really existing, active men, but stops at the abstraction "man"’.

The alternative that Marx and Engels propose is, of course, also a theory, but it is a theory, they claim, of a quite different kind. ‘In direct contrast to German philosophy, which descends from heaven to earth’, their purpose is to present an account which will ‘ascend from earth to heaven’. Instead of translating general ideas back into equally general anthropological categories, the aim is to give a specific account of their historical origins. In so doing, it undermines the presuppositions on which the philosophical enterprise rests and philosophy, as an independent branch of knowledge, loses its medium of existence:

> The philosophers would only have to dissolve their language into the ordinary language, from which it is abstracted, to recognize it as the distorted language of the actual world, and realize that neither thoughts nor language in themselves form a realm of their own, that they are only *manifestations* of actual life.
>
> (1845-6: 118)

6 The theory of ideology: (1) The reflection model

The German Ideology is filled with polemical assertions of the priority of material life over the world of religion, thought and speculation. But it sets out to do more than sloganize. Its aim is to develop the framework for a scientific explanation of how the material life conditions and determines thought and culture. By the time *The German Ideology* came to be written, the term ‘ideology’ had established itself in German as referring to systems of ideas detached from and out of proportion to empirical reality (Heinrich Heine, with whom Marx was on intimate terms in Paris, used it in that sense). In *The German Ideology* this is certainly part of the meaning of the term. But the concept also has a wider explanatory function (see Ideology).

Since the ancient world, political thinkers had been concerned with the role that ‘false’ or irrational forms of consciousness play in political life. To this extent, the Young Hegelian critique of religion represented the latest manifestation of a very long tradition. However, the originality of Marx’s concept of ideology lies in the way that it brings the idea of false consciousness together with a distinctively modern conception of society.

At the end of the eighteenth and the beginning of the nineteenth century, a conception of society came to the fore in Germany and France, according to which societies, like organisms, have the power of maintaining and reproducing themselves through time. Marx was very much taken with this view, which he endorsed in the *Critique of Hegel’s Philosophy of Right*. Chief among the conditions for a society to reproduce itself, according to Marx, are the ideas held by its members. Thus false consciousness, rather than being simply an accidental feature of human nature (albeit one with enormous political consequences) should be regarded as a phenomenon to be explained by the particular character of the society in which it is to be found.

If societies do not rest solely on coercion, then this is because those who are oppressed or exploited for some reason accept this. As Marx puts it bluntly: ‘the ideas of the ruling class are in every epoch the ruling ideas’. But how does this come about? What sort of connection holds between the economic structures of a society and the ideas of its members? *The German Ideology* contains two analogies that might serve as mechanisms for the explanation of the connection between material life and ideas. The first is embodied in the following famous passage:

> If in all ideology men and their circumstances appear upside-down as in a camera obscura, this phenomenon arises just as much from their historical life-process as the inversion of objects on the retina does from their physical life-process…. We set out from real, active men, and on the basis of their real life-process we demonstrate the development of the ideological reflexes and echoes of this life-process. The phantoms formed in the human brain are also, necessarily, sublimates of their material life-process, which is empirically verifiable and bound to material premises.
>
> (1845-6: 47)

Let us call this the 'reflection model' of ideology. The idea is that ideology relates to material life as images do to reality in a camera obscura or on the retina of the human eye: items in reality are reproduced accurately, but in reverse.

Yet brief consideration of the analogy shows that, as it stands, it is completely inadequate. It is indeed true that the images on the human retina are 'upside-down'. But does this mean that human beings do not perceive the world about them accurately? Of course not. The fact is that, as far as human perception is concerned, 'upside-down' is the right way up for images to be on our retinas. And this points the way towards the problem with Marx's analogy. By describing *all* consciousness as reversed or inverted the contrast between 'true' and 'false' loses its sense.

A further objection arises later in the quoted passage in which Marx continues the reflection analogy when he speaks of the ideological 'reflexes and echoes' of real life-processes. Ideological ideas are, he goes on to say, 'phantoms' and 'sublimates'. These metaphors carry with them an important implication: ideological thought is the effect of real processes, but it is itself insubstantial, without material reality or causal power. If this is Marx's considered view, then it is clearly disastrous for the theory of ideology. For the point of the theory of ideology was to explain how it was that certain forms of thought served to sustain particular societies. Thus these forms of thought are, by assumption, not ineffective, but have very important causal effects: helping to maintain a particular social and economic order.

Finally, it is not obvious that ideology relates to material life as mind relates to matter. Is the implication that ideology is immaterial and material life non-intellectual? This plainly contradicts Marx's basic position. Not only would it be odd for an avowed materialist to suggest that ideas are something basically insubstantial, but, even more importantly, it conflicts with the idea that economic life, so far from being unconscious or unreflective, is the central part of man's cognitive engagement with external reality.

7 The theory of ideology: (2) The interests model

There is, however, another model at work in *The German Ideology*. While the reflection model draws on the parallel between the ideological process and a traditional, realist account of perception (the immaterial mind passively mirrors a mind-independent reality) what we may call the 'interests model' develops from a more instrumentalist approach to epistemology. That Marx was (at this time, at least) attracted to such views is apparent from the 'Theses on Feuerbach'. In the second thesis he writes, 'The dispute over the reality or non-reality of thinking that is isolated from practice is a purely *scholastic* question.' From this point of view, the most significant aspect of ideas is not their relationship to a mind-independent reality, but that they are the products of practical activity, and that this practical activity is itself guided by interests. The materialistic view of history that this leads to, Marx and Engels say: 'does not explain practice from the Idea, but explains the formation of ideas from material practice'.

The problem with the interests model does not lie in the view that ideas are the product of interests itself, which is, of course, very plausible (although it is more difficult to determine just what proportion of our ideas are products of interests in this way - surely not all of them - and to explain just how it is that interests should assert themselves in the process by which ideas are formed). The problem is that ideological ideas are not simply ideas formed in the pursuit of interests. They are, in fact, supposed to be ideas that go *against* the interests of a large number of those who hold them (and in this way further the interests of others). How do ideas of this kind come to be accepted?

Marx and Engels's answer starts from the following claim:

> The class which has the means of material production at its disposal, has control at the same time over the

> means of mental production, so that thereby, generally speaking, the ideas of those who lack the means of mental production are subject to it.
>
> (1845-6: 64)

But this is not a satisfactory solution. Marx and Engels seem to view those who live under the domination of the ruling class as passive victims, taking their ideas like obedient chicks from those who control the 'means of mental production', with no critical reflection as to whether the ideas are either true or in their own rational interests. Yet why should one suppose that the ruling class is capable of promoting its interests effectively and forms its ideas in response to those interests, while the dominated classes simply accept whatever is served up to them?

Marx and Engels do, however, attempt to make their claim more plausible in their discussion of the nature of mental production. It is, they write, the most significant development in the division of labour that mental and manual labour become separated:

> Division of labour only becomes truly such from the moment when a division of material and manual labour appears…. From this moment onwards consciousness *can* really flatter itself that it is something other than consciousness of existing practice, that it *really* represents something without representing something real; from now on consciousness is in a position to emancipate itself from the world and to proceed to the formation of 'pure' theory, theology, philosophy, ethics, etc.
>
> (1845-6: 51-2)

The separation between mental and manual labour, Marx and Engels maintain, does not really lead to the formation of autonomous ideas; the ideologists who produce ideas are still part of the ruling class whose interests their ideas represent. Nevertheless, it offers an explanation as to why such ideas should be accepted by those, the dominated classes, whose interests they oppose: they are accepted because they are apparently disinterested. The ideologist, on this view, is like a bribed referee: able to influence the outcome of a game all the more effectively for the fact that he is falsely believed to be impartial.

Are ideologists, then, engaged in deception? Do they know the partiality of their ideas but present them none the less as if they were neutral and disinterested? On the contrary. According to Marx and Engels, ideologists are sincere - and, because they sincerely believe in the independence and objective validity of their own ideas, they are able to persuade others to accept them as such all the more effectively. Herein, however, lies the problem. How are we to suppose it to be true that the ideologists should both be constrained so that they produce ideas in the interests of the ruling class of which they are, appearances to the contrary, a part, and that they (and those who accept the ideas from them) remain sincerely unaware of the nature of this connection? Why do they *think* that they are independent when in fact they are not? And, if they are not independent, how do the class interests they share with the rest of the ruling class assert themselves?

In any case, it is clear why Marx should now become so hostile to philosophy: like any supposedly 'pure' theory, philosophy represents a deceptive abstraction from the particular circumstances and material interests that it serves. This move to detach ideas that are the products of material interests from the interests that they represent is epitomized, for Marx and Engels, in Kant (the 'whitewashing spokesman' of the German bourgeoisie, as they call him). Kant, they write:

> made the materially motivated determinations of the will of the French bourgeois into *pure* self-determinations of 'free will', of the will in and for itself, of the human will, and so converted it into purely ideological determinations and moral postulates.
>
> (1845-6: 99)

For Marx and Engels, at this stage at least, 'moral postulates' are, by their very nature, ideological.

8 Historical materialism

'Where speculation ends - in real life - there real, positive science begins', according to Marx and Engels in *The German Ideology*. The science to which they are referring is the materialist theory of history, whose classic statement is given in the Preface to *Zur Kritik der politischen Ökonomie (A Contribution to the Critique of Political Economy)* (1859).

Taken most generally, the materialist theory of history asserts that the manner in which human beings produce the necessities of life determines the form of the societies in which they live. Every society other than the most primitive produces a ‘surplus’ beyond what it immediately consumes. The manner in which this surplus is ‘appropriated’ - taken from the direct producers and redistributed - determines the class structure of the society in question. If society is divided between direct producers and those who benefit from the former’s ‘unpaid surplus labour’ (something that is true of all societies where a surplus exists, prior to the advent of socialism) the relationship between classes is antagonistic.

At any stage, the size of the surplus is an expression of the level of development of the ‘productive forces’ - the resources, physical and intellectual, upon which material production draws. Every society contains both an economic ‘base’, composed of ‘relations of production’ (the relations producers have to the means of production and to one another) and a legal and political ‘superstructure’, corresponding to the base. The relations of production favour the development of the productive forces up to a point. Beyond this they become, Marx says, ‘fetters’ upon the forces of production, and a conflict arises which leads eventually to the replacement of the existing relations of production with new and superior ones.

Presented in these terms, it is clear that the materialist theory of history is intended as an exercise in social science rather than philosophy. Thus it may seem surprising that it should have attracted such enduring attention on the part of philosophers. However, scientific theories may be of concern to philosophers if their assumptions are novel, obscure or questionable, even if the intentions behind them are in no way philosophical (examples are Darwin, Freud and Newton). In the case of Marx’s theory of history, it is not just the meaning of and evidence for the particular claims to be found in the theory that have been controversial. The more general issues of the form of explanation that Marx employs and the kind of entities such an explanation presupposes have been continuing matters of dispute.

Interpreters of Marx divide broadly into three groups on these questions. In the first are those for whom Marx’s theory of history is intended to be scientific in the way that any other scientific theory is. With some qualifications, the majority of the earliest Marxists (for example, Engels himself, Kautsky and Plekhanov) fall into this group. On the other hand, those who believe that there is a contrast between Marx’s conception of science and the natural sciences may be divided into those who see Marx’s theory as a transformation of Hegel’s theory of history and those for whom it is fundamentally anti-Hegelian. The most influential presentation of the former interpretation is to be found in Georg Lukács’ *History and Class Consciousness* (1921), while the latter is particularly associated with the French philosopher, Louis Althusser (see Althusser, L. §§2-3; Kautsky, K.; Lukács, G. §2; Plekhanov, G. §2).

In the late 1970s the first approach was revived in the English-speaking world by G.A. Cohen’s seminal *Karl Marx’s Theory of History: A Defence* (1978). According to Cohen, historical materialism can be presented in a way that contains nothing that should be unacceptable to anyone who accepts the legitimacy of Darwinian biology (see Darwin, C.).

The two theories are, in Cohen’s view, importantly parallel to one another, for both employ ‘functional explanation’ (see Functional explanation). When Marx says that the relations of production *correspond* to the forces of production, what he means, according to Cohen, is first that the relations are in some sense ‘good for’ the (development of the) forces and second that they obtain *because* they are good for the forces. (The same analysis, suitably adapted, applies to the correspondence between superstructure and base.) What is distinctive about Darwinian biology, however, is not just that it employs functional explanation, but that it provides a convincing account (what Cohen calls an ‘elaborating explanation’) of why its functional explanations are true: the process of natural selection. Does Marxism have an equivalent elaborating explanation?

All the indications are that it does not. In response to this, there have been two main lines of argument. One is that the theory should have (but lacks) such an explanation and that it is the task of a sympathetic reconstruction of Marx to provide one. On the other hand, it is also possible to argue that the search for what Jon Elster has called ‘micro-foundations’ is misguided (1985). Thus the functional explanations that Marx invokes in the theory of history rest on the fact that there really are collective agents (classes, for example). On this ‘collectivist’ reading it is sufficient simply to appreciate the nature of collective agency to see why collective agents should feature in

functional explanations: they have the power to act purposively to bring about their ends. No reductive 'elaborating explanation' is necessary.

To take this view is to align oneself with the second and third groups of Marx's interpreters and to affirm the fundamental gap between Marx's theory of history and the explanations of the natural sciences (where functional explanations are not simply left unelaborated). If so, the Marxist theory of history cannot draw on the general prestige of science for its justification.

9 Political economy

In contrast to his relatively brief and schematic statements concerning general history, Marx wrote very extensively about the economic system under which he himself lived. *Das Kapital*, which presents Marx's definitive analysis of capitalism, is a work of exceptional methodological complexity, as is already suggested by its sub-title, 'Critique of Political Economy'. The phrase is ambiguous. Is Marx's objective to criticize the bourgeois economy or bourgeois economics? In fact, Marx rejects this as a false antithesis: the subject matter of the book is both. Ten years before its publication, Marx described the work that was to become *Das Kapital* in a letter: 'The…work in question is a *critique of the economic categories*, or, if you like, the system of bourgeois economy critically presented. It is a presentation [*Darstellung*] of the system and, simultaneously, a critique of it'.

The two aspects go together in Marx's view because economic categories are not simply the means employed by an observer to classify some inert mass of data. They are themselves a part of social reality, 'abstract forms' of the social relations of production.

Bourgeois economists, Marx alleges, characteristically fail to recognize that their categories are specific to capitalism, and so they treat the capitalist mode of production as one 'eternally fixed by nature for every state of society', Marx alleges. A 'critical presentation' of economics must counteract the false eternalization of the economy that bourgeois economics carries within itself.

As it stands, this is a criticism of the limitations in the self-understanding of bourgeois economics rather than a challenge to its empirical content. Yet empirical explanation is a central part of Marx's project. 'It is', he writes in the Preface to *Das Kapital*, 'the ultimate aim of this work to lay bare the economic law of motion of modern society.' Has bourgeois economics failed to discover this law or has it simply not put its categories in historical context? At its strongest, Marx's case is that both criticisms are true and that the former failing is a result of the latter. The 'law of value' that Marx claims to have discovered could not, he says, have been discovered by economic science 'so long as it is stuck in its bourgeois skin'.

The connection that Marx sees between the categories of economic life and the categories of economic analysis is made more complicated by the structure that he ascribes to capitalism. Marx believes that an indispensable ingredient for understanding capitalism is the contrast between its 'essence' - its underlying determinants - and its 'appearance' - the way that it immediately strikes those who live in it. Corresponding to this distinction are two kinds of bourgeois economic thought: what Marx calls 'classical economy', on the one hand, and 'vulgar economy' on the other. Classical economy (the tradition whose greatest representatives were Ricardo and Adam Smith) aims towards the essence of capitalism: it 'nearly touches the true relation of things', although it is not able to formulate that relation explicitly. According to Marx, it is the mark of the 'vulgar economy' of his own time, by contrast, that it 'feels particularly at home in the alienated outward appearances of economic relations'. Yet this means that it is fundamentally unscientific, for 'all science would be superfluous if the outward appearance and the essence of things coincided'. A truly scientific political economy must go beyond the immediately received categories of economic life. This is what Marx believes that he himself has achieved (and he considers himself for this reason to be the heir of the tradition of classical political economy).

In a letter to Engels, written at the time of the publication of the first volume of *Das Kapital*, Marx singles out what he calls the 'twofold character of labour' as the most important point in his book. Labour, Marx claims, is both the source of value and, at the same time, under capitalism, a commodity itself. Yet this commodity (labour-power, as Marx calls it) is a commodity of a special kind. Its value is not the same as the value of the commodities produced by the labour that is exercised on behalf of its purchaser, the capitalist. This discrepancy, in Marx's view, explains the 'origin' of surplus-value - the fact that the capitalist appropriates the surplus-labour of the worker under the guise of a fair exchange. In discussing the manner in which, in capitalist society, labour is

sold to capitalists as a commodity, in exchange for wages, Marx writes: ‘Hence we may understand the decisive importance of the transformation of the value and price of labour-power into the form of wages, or into the value and price of labour itself. This phenomenal form, which makes the actual relation invisible, and, indeed, shows the direct opposite of that relation, forms the basis of all the juridical notions of both labourer and capitalist, of all the mystifications of the capitalist mode of production, of all its illusions as to liberty, of all the apologetic shifts of the vulgar economists’.

Thus we see Marx making three claims: (1) that we should see reality as layered, having a surface appearance governed by an underlying structure; (2) that to make such a distinction is characteristic of the scientific approach to reality in general; and (3) that the phenomenal form conceals the real relations (it ‘makes the actual relation invisible and indeed shows the opposite of that relation’).

However, claims (1) and (2) do not entail (3). According to claims (1) and (2) (in themselves extremely plausible) the way that we see the world is not, immediately, adequate for us to explain the way that the world is. But that does not make our immediate perception of the world false. It simply lacks a theory. Yet Marx’s claim (3) is much stronger: reality presents itself in a way that deceives those who immediately perceive it. Marx’s own statements to the contrary, it seems that this third claim is best understood not as a general consequence of the nature of scientific understanding but as a specific feature of capitalism. Capitalism mystifies those who live under it, Marx believes, because it is a ‘deceptive object’. To penetrate its surface scientifically it is necessary to go beyond the limitations of bourgeois political economy.

10 The fetishism of commodities

The most detailed discussion that Marx provides of a case where the surface of capitalism presents itself as ‘false’ is to be found in ‘The Fetishism of Commodities and the Secret Thereof’, in *Das Kapital*. This discussion is a recognizable reworking of the central themes to be found in the treatment of alienated labour in the *Paris Manuscripts*.

In the eighteenth-century sense of the term, fetishists were those non-European peoples whose religion involved the worship of inanimate objects. Fetishism is a fallacy attributing to objects in the world some quality (power and personality) that they, in fact, lack. Marx’s conception of commodity fetishism shares this structure, but differs in an important way. The fetishism of commodities is not a matter of subjective delusion or irrationality on the part of perceivers, but is somehow embedded in the reality that they face.

According to Marx, two separate facts or properties are distorted in the commodity-form. First, the ‘social character’ of human beings’ labour appears (falsely) as ‘objective characteristics of the products themselves’, and second (in consequence of the first fact, as Marx asserts) the producers’ own relationship to their ‘collective labour’ appears ‘as a social relationship between objects, existing externally to the producers’.

The first issue concerns what the ‘social character’ that is apparently a property of the products themselves amounts to. Is it the sheer fact that the commodity *is* a commodity? This suggestion must be rejected, for the belief that the product is a commodity is in no way a false or deceptive one. Likewise, it cannot be something concealed from the producers that commodities *do* as a matter of fact exchange for one another in certain proportions: it is hard to see how anyone could live their lives within a market society without having an adequate understanding of facts of this kind (enough, at least, to be able to buy something to eat). The best interpretation of Marx’s argument is that it is not such first-order facts about commodities but a second-order one that is the source of deception: it is not *that* commodities can be exchanged with one another in certain ratios but *the reason why* they exchange in the ratios that they do that is their hidden secret.

Marx’s account of the illusion regarding the social character of the products of labour is complemented by the account he gives of the second element in commodity fetishism. Because commodity production takes place as a process by which the producers’ activities are coordinated solely through the imperatives of a system of market exchanges, it follows, Marx says, that ‘the social relations between their private acts of labour manifest themselves as what they are - that is, not as the immediate social relationships of persons in their labour but as material relationships between persons and social relationships between things’.

Implicitly, the market commensurates the labour of each individual with the labour of every other producer -

individual labour has its value in relation to the way in which others perform the same labour. The socially useful character of the labour of the individual producers thus appears to them, according to Marx, 'only under those forms which are impressed upon that labour in everyday practice, in the exchange of products'.

Here again, Marx is indicating an illusion of the second rather than the first order. The individual producers are aware of the role of the market in determining the way in which they labour. In this they are quite correct. But they also believe (falsely) that it is the market that makes their labour useful (rather than recognizing it as a contingent fact about capitalist production that their socially useful labour takes on a market-determined form). Society generates such false beliefs spontaneously, Marx claims. The world of commodities 'veils rather than reveals', he says, the social character of private labour and of the relations between the individual producers.

That the true source of the value of commodities lies in the labour expended in their production is, Marx maintains, a matter of simple scientific truth. So, too, is the fact that the social character of private labour consists in the equalization of that labour under the auspices of the market. Nevertheless, fetishism is a matter of 'objective illusion' and knowledge of these truths does not dispel such false appearance. The discovery of the law of value 'by no means dissipates the objective illusion through which the social character of labour appears to be an objective character of the products themselves' any more than 'the discovery by science of the component gases of air' altered the atmosphere that people breathed.

The analogy that Marx chooses here is not a happy one. Admittedly, it is absurd to think that a scientist's discovery about an object should change the object itself. But that is not the issue. It is not a question of whether the atmosphere itself changes after the discovery of its component gases, but whether the way in which we think about it changes. It is only if we suppose that capitalism, unlike the atmosphere, is an object of a particular kind - a deceptive object - that it is possible to claim that it will continue to encourage such false beliefs in the face of contrary knowledge.

But it is not just that the individuals who live in a society based on commodity production are deceived by it regarding the way that it works. The way that it works is itself criticized by Marx. Above all, the 'social character of labour' is made private in actuality. This is not a misperception or false belief, but a contradiction: a discrepancy between what Marx takes to be the intrinsic nature of social labour and the way that it is in fact organized. Capitalism is not just deceptive, but also defective.

11 Morality

The question whether Marx's theory has a moral or ethical dimension is one of the most controversial of all issues surrounding the interpretation of his work, and the difficulty facing interpreters is easily seen. On the one hand, Marx has a number of uncompromisingly negative things to say about morality. Moreover, after 1845 at least, he affirms that his own theory is not a utopian or ethical one but 'real, positive science'. Yet, on the other hand, much of the language that he uses to describe capitalism is plainly condemnatory (for instance, that it is antagonistic, oppressive and exploitative). Does this not represent an inconsistency on Marx's part? Is he not moralizing and rejecting morality at the same time?

This section will present a line of interpretation according to which Marx is not inconsistent. The interpretation depends on a contrast between certain doctrines typical of moral philosophy (which, it will be argued, Marx rejects) and the rejection of ethical values as such (to which, it will be argued, he is not thereby committed). However, it should be noted that this interpretation is controversial and involves considerable reconstruction of the rather sparse evidence that we have of Marx's views.

It is helpful to start, as Marx himself did, with Hegel's critique of Kant. Both Marx and Hegel share the belief that morality, as embodied in Kant's moral philosophy, is, as they put it, 'abstract' (see Hegel, G.W.F. §8). There appear to be three interconnected elements compressed into this criticism:

(1) First, morality is alleged to be abstract in the sense that it contains principles expressed in universal form (in Kant's case, the 'categorical imperative' to 'act only according to that maxim which you can, at the same time, will to be a universal law' (see Kantian ethics)). While such principles may function as a test upon proposed actions, they do not, the argument goes, determine the content of the action to be performed. Thus, the claims of moral philosophy to the contrary, specific content is surreptitiously imported into ethics from the existing

institutions or codes of behaviour of the society in question.

(2) Second, morality is abstract to the extent that it takes the form of a mere injunction: an imperative that is addressed to people's 'moral reason', telling them to act in a certain way because that is 'good in itself'. Moral action is detached thereby from other forms of human action and, as a result, moral theory has nothing to say about the conditions under which the forms of behaviour that it commends will be realized in practice.

(3) Finally, morality may be said to be abstract in that it contains an unhistorical understanding of its own status. It presents its principles as if they were the axioms of some timeless moral geometry. Yet, in fact, every system of morality is a way of seeing the world that arises in particular circumstances and responds to definite needs within those circumstances.

Although one or more of these features may be present in the forms of moral philosophy with which we are most familiar, it is not clear that they are a necessary feature of every view that one might call 'moral'. Not all ethical positions have to express themselves as systems of universal principles that we are enjoined to follow because they are good for their own sake. Admittedly, many philosophers would argue that to combine the value commitments characteristic of morality with the meta-level doctrine that such values are, in the end, expressions of interest (Marx's version of (3) above) inevitably undermines, as Nietzsche might have put it, the value of value itself. But it is at least arguable that the two standpoints are compatible. The path from sociological determinism to moral scepticism is not as steep, slippery and remorseless as it is sometimes claimed to be.

If this is conceded, we can draw a distinction between morality in two senses: morality as a quasi-Kantian system of principles (which Marx rejects) and morality as a set of values embodying a conception of what is good for human beings (which he can consistently accept). To present things in this way, however, may seem to give insufficient weight to the vehement hostility which Marx shows towards ideas of justice and rights, in particular. On the interpretation being proposed here, Marx's animus is best understood as aimed at what he sees as the assumptions behind such values, rather than at the fact of their being values as such.

Roughly speaking, we may think of rights as things that permit individuals to act in certain ways, in given circumstances, should they wish to do so, and to be able to claim correlative duties on the part of others. A duty, correspondingly, would require individuals to act in some way, whether they wished to or not. Justice (if we do not think of it simply as a matter of rights and duties) would consist of principles on which benefits and burdens are distributed in cases where interests conflict.

What these values have in common is that they provide a framework which regulates and limits the self-seeking behaviour of individuals. They are values that assume a conflict between (to put it in Kantian terms) 'duty' and 'inclination'. Just as Marx supposes that the categories of bourgeois economics eternalize the forms of bourgeois economic life, so, he believes, discussion of rights (which he denounces in the *Critique of the Gotha Programme* as 'ideological nonsense') eternalizes a situation in which the good of each individual is independent and so can only be advanced at the expense of others. Right, moreover, can only apply a fixed and equal standard to unequal individuals, 'from outside'.

For the liberal, who is concerned to protect the individual's powers of self-direction against the intrusions of others, the attraction of the idea of rights is that it presupposes nothing about individuals' characters and personalities. For Marx, on the other hand, that is just its weakness: rights do nothing to transform human nature. Against this, it is clear that Marx, from the time of the *Paris Manuscripts*, sees social progress as characterized by a form of community in which (as he and Engels put it in the *Communist Manifesto*) 'the free development of each is the condition for the free development of all'. Marx's ethical ideal is one of solidarity in which all advance together.

Hence Marx's reluctance to use the language of justice to condemn capitalism becomes more intelligible. It is not that Marx thinks that exploitation, expropriation, oppression, slavery and misery (a few of the terms he applies to the capitalist system) are *just*. But he is reluctant to use language that would suggest that these are forms of injustice for which 'justice' (in the sense of giving 'each their due') is the final and sufficient remedy.

12 Socialism

It may seem odd, given that Marx devoted his life to the achievement of a socialist society, how brief and

unspecific his accounts of it are. One explanation that is often advanced for this apparent neglect is the following. Marx believed, it is said, that thought is limited to its own time. Thus it would have been improper for him, living under capitalism, to try to anticipate the nature of the society that would replace it and to write (as he puts it in the Preface to the Second Edition of *Das Kapital*) 'recipes for the cook-shops of the future'. While this may be part of the reason for Marx's reticence, it cannot alone suffice. For, even if we grant that Marx believed that each stage of society sets a boundary which thought cannot cross (and it is by no means beyond question that he did hold this view in such a strong form) he is also committed to the view that socialism is anticipated within capitalism.

In the Preface to *Zur Kritik der politischen Ökonomie* Marx makes the general claim that new forms of society are always prefigured within the old ones that they replace. 'Mankind', he writes, 'only sets itself such tasks as it is able to solve, since closer examination will always show that the problem itself arises only when the material conditions for its solution are already present or at least in the course of formation'.

Marx describes the process by which capitalism prepares the ground for socialism at the end of the first volume of *Das Kapital*. As the productive forces developed by capitalism grow, he claims, so too does the 'mass of misery, oppression, slavery, degradation, exploitation'. A stage is reached, however, at which the monopoly of capital becomes a 'fetter' on production and 'the centralization of the means of production and the socialization of labour at last reach a point where they become incompatible with their capitalist shell'. At this point, the shell 'bursts asunder', the 'death knell' sounds for capitalism and the 'expropriators are themselves expropriated'.

The first and most obvious difference between capitalism and socialism is that common ownership leads to a quite different pattern of distribution of the products of labour. No longer will the capitalist, in virtue of his ownership of the means of production, be able to exploit the individual producer. In the *Critique of the Gotha Programme* Marx distinguishes two stages of post-capitalist society. In the first, the direct producer receives back from society (after deductions for shared costs and social expenditure) 'what he has given to it as his individual quantum of labour'.

But this, Marx points out, is a principle of distribution that merely rectifies exploitation. It does not remedy the inequalities that arise from contingent differences in natural capacities between individual producers. Later, however, society will move beyond this, Marx claims, and 'the narrow horizon of bourgeois right' will be 'crossed in its entirety'. At this point, the principle upon which society will operate will be: 'From each according to his ability, to each according to his needs!' But socialism is distinguished by more than its principle of distribution. In particular, labour will be organized quite differently from the way that it is organized under capitalism.

One of Marx's few reasonably extensive accounts of the nature of the socialist organization of production is to be found in the section on the fetishism of commodities in *Das Kapital*, as part of a comparison between capitalist and other forms of production. Marx starts with Robinson Crusoe, whose productive activity he describes as 'simple and clear'. For Robinson, Marx says, the organization of production is a purely administrative operation: the end is known, as are the resources available and the techniques by which that end could be attained. Marx then moves from 'Robinson's island, bathed in light', via feudal and patriarchal forms of production, before alighting on: 'a community of free individuals, carrying on their labour with the means of production in common, in which the labour-power of all the different individuals is consciously applied as the combined labour-power of the community'.

Here, Marx says,

> All the characteristics of Robinson's labour are…repeated, but with this difference, that they are social, instead of individual…The social relations of the individual producers to their labour and to the products of their labour remain here transparently simple, in production as well as in distribution.
>
> (1867-: 171-2)

The idea that labour could be 'consciously applied' in a complex modern society - resources and needs coordinated, efficient techniques adopted, innovation managed - with the same 'transparent simplicity' as an individual allocating his time to different tasks on a desert island is astonishingly implausible. And, even if it were not so, the question would still arise how that 'common and rational plan' (as Marx terms it elsewhere) would relate to the individuals whose task it was to carry it out. Would it not, from their point of view, be no less of an 'external' imperative to be followed than the dictates of the market that govern their labour under capitalism?

Arguably, the idea that society under socialism would be spontaneously unified like one great, self-transparent super-individual represents an unacknowledged hangover in Marx's mature thought from Hegel's doctrine of *Geist*. However that may be, the presence of this doctrine goes a long way towards explaining why Marx had so little to say about the problems of socialist economic organization: he simply failed to see the difficulty. Few theoretical omissions, surely, have ever had more disastrous historical consequences.

MICHAEL ROSEN

List of works

Marx, K. and Engels, F. (1975-) *Gesamtausgabe* (*MEGA*), Berlin: Dietz.(This outstanding edition of the collected works is often known as *MEGA* II. However, at the time of writing, *MEGA* II, like *MEGA* I, seems likely to remain uncompleted.)

Marx, K. and Engels, F. (1961-83) *Werke* (*MEW*), Berlin: Dietz.(A very adequate edition in German that contains all the works referred to in the text of the entry.)

Marx, K. and Engels, F. (1975-) *Collected Works*, London: Lawrence & Wishart.(A complete edition in English. Marred, however, by patchy and dogmatic editorial work and poor translations. Other editions are generally to be preferred, if available.)

Marx, K. (1975-) *The Pelican Marx Library*, Harmondsworth: Penguin.(Not a complete edition, but a series that contains particularly good translations of *Das Kapital*, the *Grundrisse*, and the *Early Writings*, among others.)

Marx, K. (1841) *Differenz der demokritischen und epikureischen Naturphilosophie*, trans. *Difference between the Democritean and Epicurean Philosophy of Nature*, in *Collected Works*, London: Lawrence & Wishart, 1975-, vol. 1, 25-107.(Marx's doctoral dissertation.)

Marx, K. (1843a) *Zur Kritik der Hegelschen Rechtsphilosophie*, trans. R. Livingstone and G. Benton, *Critique of Hegel's Philosophy of Right*, in L. Colletti (ed.) *Early Writings*, Harmondsworth: Penguin, 1975, 57-198.(An extensive discussion of Hegel, abandoned by Marx.)

Marx, K. (1843b) 'Zur Judenfrage', trans. R. Livingston and G Benton, 'On the Jewish Question', in L. Coletti (ed.)*Early Writings*, Harmondsworth: Penguin, 1975, 211-42. (An important treatment of the idea of emancipation.)

Marx, K. (1844) *The Paris Manuscripts*, trans. R. Livingston and G. Benton in L. Coletti (ed.) *Early Writings*, Harmondsworth: Penguin, 1975, 279-400.(Contains Marx's ideas on alienation.)

Marx, K. and Engels, F. (1845a) *Die Heilige Familie*, trans. *The Holy Family*, in *Collected Works*, London: Lawrence & Wishart, 1975-, vol. 4, 15-211.(A polemic against Bruno Bauer and his associates.)

Marx, K. (1845b) 'Theses on Feuerbach', trans. R. Livingston and G. Benton in L. Coletti (ed.) *Early Writings*, Harmondsworth: Penguin, 1975, 421-3.(Brilliant aphorisms on philosophy.)

Marx, K. and Engels, F. (1845-6) *Die Deutsche Ideologie*, ed. C.J. Arthur, trans. *The German Ideology*, London: Lawrence & Wishart, 1970.(A well-produced version of this key work.)

Marx, K. (1847) *La Misère de la Philosophie*, trans. *The Poverty of Philosophy*, in *Collected Works*, London: Lawrence & Wishart, 1975-, vol. 6, 105-212.(Polemic against Proudhon.)

Marx, K. and Engels, F. (1848) *Das Kommunistische Manifest*, trans. *The Communist Manifesto*, in D. Fernbach (ed.) *The Revolutions of 1848*, Harmondsworth: Penguin, 1973, 62-98.(The classic statement of Marx's political and social programme.)

Marx, K. (1850) *Die Klassenkämpfe in Frankreich*, trans. *Class Struggles in France*, in D. Fernbach (ed.) *Surveys From Exile*, Harmondsworth: Penguin, 1973, 35-142. (Commentary on contemporary politics.)

Marx, K. (1852) *Das achtzehnte Brumaire des Louis Bonaparte*, trans. *The Eighteenth Brumaire of Louis Bonaparte*, in D. Fernbach (ed.) *Surveys From Exile*, Harmondsworth: Penguin, 1973, 143-249.(Commentary on contemporary politics.)

Marx, K. (1857-8) *Grundrisse der Kritik der politischen Ökonomie*, trans. M. Nicholas, *Grundrisse*, Harmondsworth: Penguin, 1973.(An abandoned draft on political economy - superseded by *Das Kapital*.)

Marx, K. (1859) *Zur Kritik der politischen Ökonomie*, trans. as *A Contribution to the Critique of Political Economy*, in *The Pelican Marx Library*, Harmondsworth: Penguin, 1975-.(Contains the classic statement of 'historical materialism'.)

Marx, K. (1862-3) *Theorien über den Mehrwert*, trans. E. Burns, *Theories of Surplus-Value*, London: Lawrence

& Wishart, 1963, 3 vols.(Marx's studies on economic theory.)
Marx, K. (1867-) *Das Kapital*, trans. B. Foukes, *Capital*, Harmondsworth: Penguin, 1977.(Marx's mature masterpiece.)
Marx, K. (1871) *Der Französische Bürgerkrieg*, trans. *The Civil War in France*, in D. Fernbach (ed.) *The First International and After*, 1973, 187-268.(An important political text.)
Marx, K. (1875) *Kritik des Gothaer Programms*, trans. *The Critique of the Gotha Programme*, in D. Fernbach (ed.) *The First International and After*, 1973, 339-59. (Contains a rare, brief discussion of the nature of socialism.)
Marx, K. (1977) *Selected Writings*, ed. D. McLellan, Oxford: Oxford University Press.(At the time of writing, probably the best of the many good selections from Marx's work available.)

Marxism, Chinese

Chinese Marxism is a mixture of elements from Confucianism, German Marxism, Soviet Leninism and China's own guerrilla experience. Because Mao Zedong (1893-1976) was in power longer than any other Chinese communist, the phrase 'Chinese Marxism' is commonly used to refer to Mao's own evolving mixture of ideas from these sources. However, the advocates of Chinese Marxism have come from many different factional backgrounds and have tended to emphasize different aspects in their own thinking. Even Maoism reflects many minds. For example, Mao's two most famous essays, 'Shijianlun' ('On Practice') *and* 'Maodunlun' ('On Contradiction') *(1937) drew heavily from Ai Siqi, the author of the popular philosophical work Dazhong zhexue (Philosophy for the Masses) (1934).*

The goals of the Chinese Marxists included the salvation of China from its foreign enemies and the strengthening of the country through modernization. Accordingly, they selected from other systematic theories those doctrines that appeared to facilitate those goals, and then paired these doctrines with others from theories that were sometimes incompatible. One should not, therefore, look for logical consistency in the relations between the ideas that the Chinese Marxists drew from these various sources.

The foundation of Chinese Marxism was undoubtedly Marx's materialist conception of history, and the concepts of class struggle and control of the forces of production shaped the thinking of many early Marxists. However, faced with the need to accelerate social change through class struggle rather than waiting for the full flowering of capitalism, Marxists such as Li Dazhao began focusing less on materialism or determinism and more on voluntarism. There also arose a doctrine, based on the ideas of Lenin and Trotsky, that right-minded people could 'telescope' the phases of the revolution and hasten the transition through the historical stages. This ultimately led to the doctrine of permanent revolution. First promulgated in China in the late 1920s, it reappeared in the 1950s. After Mao's death, the 'subjectivity' movement within Chinese Marxism sought to move the focus away from classes or groups and onto the individual subject as an active agent.

Throughout the evolution of Chinese Marxism, political struggles played a direct role in the formulation and discussion of philosophical positions. Mao's epistemological essay 'Shijianlun' *clearly reflects the experience of leaders during the guerrilla period, and his theories of knowledge are analogous to the 'democracy' practised by the guerrilla leaders: the people were consulted for their knowledge and opinions, decisions were then made from the centre, and the resulting policies were taken back to the masses through teaching. In the same way, Mao believed, individuals perceive through their senses, form theories in their brains (the centre), and test the resulting theories in a manner analogous to teaching.*

In China, right minds among the people were thought to arise through officials teaching the people. Here pre-modern Confucian legacy becomes important. It helps to explain the endurance of teaching as an official function in the Chinese Marxist discussion of democratic centralism. In Confucianism, the primary function of government was education, although it certainly had other tasks, such as the collection of taxes. All officials, including the emperor, had the task of transforming the character of the people. The education in which the state involved itself, through control of the curriculum and national examinations for the civil service, was moral education. The ultimate aim of state-controlled Confucian education was a one-minded, hierarchical society, meaning that people of all different strata would think the same on important matters. Maoists also sought to create a one-minded people through officially controlled teaching.

If the focus of teaching is on right ideas, which are supposed to motivate people towards socialism, one such idea in later Maoist writing is egalitarianism of social status. This was challenged by others, notably Liu Shaoqi, and following Deng Xiaoping's assumption of power in 1978 it suffered a further blow with the switch in economic policy from central planning to market forces.

An example of the relevance of political struggle to the formulation of ideas was the heightening of the campaign against the philosophy called 'humanism', following a dispute in 1957 between Mao and President Liu Shaoqi. Liu made a speech in April of that year saying that capitalists had changed and so class struggle against them could be minimized; this was followed by a Maoist-inspired attack on humanism as a philosophy. The humanism that the Maoists attacked was a Confucian-inspired belief in a class-transcending humaneness or compassion for

humankind or humaneness. In contrast, in the post-Mao years, the content of humanism has altered, and the term has come to refer to a doctrine inspired by both the early Marx and by the Western psychologist Maslow, namely that the goal of society is the individual's self-realization. This form of humanism is one of several competing positions that claim to carry on the Marxist tradition in new directions, and has been reinforced by one form of the subjectivity movement in the Deng Xiaoping era.

1 Historical materialism

It was the German theories of Marx that furnished the vocabulary from which Chinese Marxists gradually developed their positions. The key expressions are the building blocks of Marx's 'materialist conception of history', found in the preface to his *A Contribution to the Critique of Political Economy* (1858). Here, Marx argues that human societies evolve progressively through historical stages and that there is an agent of change that propels them from one stage to another. This agent is the struggle between social classes ('relations of production') that have differing power ties to property, especially to property used in production. This class struggle begins when the existing class structure prevents further development of the technology used in making tools ('forces of production'). The combination of classes and tool technology constitutes the 'foundation' or base; everything significant that humans believe (their ideologies or 'consciousness') in the realms of legal, political, religious and aesthetic matters, plus the institutions that embody them, are the 'superstructures'. In this formulation, the materialist conception of history suggests that the base determines the superstructure. What we believe is determined by economic factors, the classes and tools.

The class that has the most advanced beliefs leads a society from one stage to the next. However, there is an inevitable sequence in this historical progression. There must first be economic development (in Marx's time, this meant the flowering of capitalism), then the acquisition of consciousness by the emerging social class that capitalism fetters (the proletariat), and only then can that progressive proletarian class carry out its struggle to move society forward.

The founders of the Chinese Communist Party included Li Dazhao (1888-1927) and Chen Duxiu (1879-1942). Li, once chief librarian at Beijing University, was later the first communist to join the Guomindang. Chen had been an editor of the influential journal *New Youth* and initially advocated guild socialism under the influence of John Dewey. Li was at first only critically receptive to Marxism; although he accepted the need for class struggle, he viewed it as a sign of human evil. Marxism itself, he felt, lacked an ethical perspective. Good persons emerge as they learn mutual aid, a principle not stressed by Marx.

The early Chinese Marxists did ultimately retain the idea of a glorious future for China, a future guaranteed by the progressive view of history and embodied in historical materialism and the dynamics of class struggle. However, the sequence of the historical theory, the fact that a full flowering of capitalism was required before the agents of change could begin to guide the struggle to create a new society, caused problems. This process could take a long time in industrially backward China. During the years 1919 and 1920, many of the earliest Chinese Marxists, such as Li Dazhao, focused on economic determinism and were troubled by it. In an attempt to find a solution they turned to other theories, selecting those doctrines that appeared to facilitate their goals.

One such example of selective borrowing took from German Marxism. Li Dazhao and certain other Chinese Marxists played down base-superstructure determinism and the idea of the inevitable sequence of events (right ideas follow upon full economic development, and leadership of revolutionary struggle follows consciousness of those ideas) with which it was associated. They eliminated those parts that comprised the materialist conception of history, as well as the notion that historical stages are of long duration and that classes are to be defined solely in economic terms. Instead, they took the position that human consciousness or the minds of right-thinking, strong-willed persons can determine the future. This is voluntarism, the power of the conscious will (*voluntas*) to change the material world. In taking this position, Li and the others were influenced by non-Marxist intellectual currents in China, including even anarchism.

Although economic determinism in the Chinese Marxist theory of history faded, this did not mean the total disappearance of the economic variables in that determinism from the theories of the Marxist community. For example, enduring variables encompassed some economic determinants used in class analysis. These included differentiating urban factory proletarians from rural peasantry, and defining poor peasants in terms of amount of

farm tools and animals owned. Another example is the explanation of historical stages in terms of the transition from one form of property ownership (bourgeois/capitalist) to another (socialist). Ideological disputes often centred on the nature of some of these economic variables, such as on the duration of stages. For example, Chen Duxiu initially opposed an alliance of the communists and the Guomindang in the 1920s, which was promoted by the USSR. He eventually accepted the alliance, while at the same time trying to preserve the independence of the communists, but he proclaimed that China would need a long capitalist/bourgeois stage before socialism could be achieved. During this period, Chen wanted the communists to focus on education in a multi-party state that protected civil rights. He regarded armed class uprisings at this stage as foolish.

Other factional disputes within the leadership centred on which economically-defined class was to play the dominant role in the revolution. As early as 1926, while the Communist International stressed organizing the urban proletariat, Mao saw the potential of peasant associations, believing that peasants could be successful agents of the communist revolution. In contrast, Li Lisan wanted the urban proletariat to control the rural communist councils. In 1931 came the end of the communist movement in the cities and the shift to rural areas. Mao's doctrine prevailed: the 'peasants' have proletarian ideas, and thus class definition came to be defined partly in economic terms and partly in terms of consciousness.

The voluntarist position that replaced economic determinism gradually became intertwined with another doctrine, that concerning the ability of right-minded people to telescope the process of transition through historical stages. This new doctrine drew elements from a thesis popularly associated with Trotsky, the theory of permanent revolution, from which Mao had nominally distanced himself. Trotsky in turn had borrowed most of the essentials of this theory from Marx and Lenin. This voluntaristic, unacknowledged theory of permanent revolution came to coexist with what was left of historical materialism in China after the unacceptable parts were eliminated. It is completely incompatible with the original German formulation of historical materialism and economic determinism that had so fascinated the first Chinese Marxists.

2 Permanent revolution

Impatient to move China into its safe and prosperous future, first Li Dazhao and then Mao Zedong adopted a stance that had been foreshadowed by Marx (in his 'Address of the Central Committee to the Communist League' in 1850), and then by Lenin (in 'Two Tactics of Social Democracy in the Democratic Revolution'). The voluntarist theories of Li and Mao changed the agent that precipitates class struggle in historical materialism. No longer was this agent the tension between tool technology and class structure; rather, it was the ideas in the minds either of a few elites who teach the masses (in the view of Mao), or of those elites aided by some positive ideas already in the minds of almost all Chinese people (in the view of Li). Armed with these ideas, elites can telescope the course of history, shortening the normal duration of a historical stage. They can do so by taking control of the historical period that really should be led by the capitalists. Although Mao and Liu Shaoqi did not start regularly using the term 'uninterrupted' (permanent) to describe revolution and society until the 1950s, Mao had accepted the principles of this doctrine of permanent revolution in the 1930s.

In this view, then, China does not need to wait for capitalism to flower before the right ideas enter the minds of its people; the elite can acquire the right ideas rapidly and proceed to lead the class struggle, take over leadership of the revolution and introduce socialism. This revolution is permanent in the sense that the attainment of one stage (bourgeois democracy) is not followed by a long period of peace and gradual growth into the next. Rather (and this was Lenin's contribution), the struggle that ushered in the new stage continues, as the few leaders with the right ideas take power away from those that would seem to be in charge (capitalists) and rapidly accelerate people into the new historical (socialist) phase.

Li Dazhao foreshadowed the doctrines of Mao Zedong in important ways. First, he highlighted revolutionary consciousness as being able to arise independently of the existence of either a large capitalist or proletarian class. The correct ideas in the minds of even a small progressive class (the communists) could accelerate China's economic and social development. Second, he defined class partially in terms of the ideas in minds. Thus, as Maurice Meisner (1967) showed, it is permissible to speak of proletarian ('progressive') ideas in the minds of most Chinese people (who are peasants) as a result of their experience with foreign 'imperialists'. Third, in Li's view, China's revolution would be peasant-based rather than based on urban workers. China could change rapidly through class struggle. The agent that would initiate class struggle and modernize China was ideas in the minds of

peasants or of most Chinese, a reversal of the sequence in historical materialism.

Mao differed from Li Dazhao in being China’s quintessential Leninist. In his view, the right ideas are originally the exclusive preserve of a small elite within the Communist Party, rather than being more widely shared among the people. Mao also differed from Trotsky and other advocates of permanent revolution in identifying a democratic or bourgeois stage for China. This is an insignificant difference, however, because for Mao, such a stage (described in his 1940 essay ‘Xin minzhu zhuyilun’ (‘On New Democracy’)) would last only a few years and would be controlled by the communists as much as possible. In fact, according to Mao, socialism was achieved and new democracy ended in 1955.

Not all of the early Chinese Marxists advocated the power of the mind to change objective conditions as strongly as did Li and Mao. This particular aspect of permanent revolution is less pronounced in, for example, the writings of Ai Siqi, the author of the popular philosophical work *Dazhong zhexue (Philosophy for the Masses)* and a resident ideologist in the Yenan guerrilla base.

3 Democracy, centralism and epistemology

The bridge between permanent revolution on the one hand, and democracy and epistemology as topics for study on the other hand, lies in the need for those who already have access to correct ideas to teach and thereby mobilize those who do not. Together, they initiate the struggle that modernizes China. Teaching is required by permanent revolution, a dictum reinforced by Confucian views on the role of rulers. The content of what is taught, or the epistemological element, derives in part from the Chinese Marxist understanding of democracy.

Ideas about democracy and epistemology in Chinese Marxism owe as much to the guerrilla experience of the 1930s and 1940s as they do to Lenin’s earlier insistence on the subordination of party debate to central leadership positions once decisions are made. In north China, the communists were dependent on local peasants for logistical support (avoiding long supply lines that could be cut) and for intelligence about the movements of Japanese and Guomindang troops. Being dependent, they had to maintain good relations with the local people. This is the origin of the communist custom of living with and consulting with the people about non-military and military matters.

Mao believed that the origin of knowledge lies in practice. Although he referred to production and science as forms of practice, uppermost in importance was the practical experience of conducting class struggle. Thus Mao regarded the knowledge of the Chinese people as developing in part during the guerrilla struggles with the Japanese and the Guomindang (in spite of the United Front with the latter, during which the communists and the Guomindang fought together against the Japanese). Democracy and centralism are forms of relationship between party officials and masses that generate knowledge in the course of the class struggle.

Mao understood the term ‘democracy’ to mean letting ordinary people speak out on topics about which they have some direct knowledge. They have useful concrete information that can help officials make good policies. Letting them speak out also helps to unify the party and the people; it promotes cohesiveness. Thus democracy is a useful tool for leaders to employ.

The expression ‘mass line’ arose during the guerrilla period to refer to the custom of consulting with local people or carrying out local investigations prior to expanding operations to a larger area, where that locally-derived information would be applicable. ‘From the masses’ is part of a slogan, and it refers to this grass roots consultation. Thus, for Chinese Marxists this aspect of the mass line practice embodied ‘democracy’. Typical of the Maoist form of Chinese Marxism is the position that ‘masses’ refers primarily to the peasantry, a source of important raw data.

There is another aspect to the mass line, indicated by the rest of the slogan (‘to the masses’), which refers to leadership, guidance or, especially, teaching by officials about policy for the local people. This takes place after prior consultation at headquarters, where the authority of centralism prevails.

In Maoist Marxism, the ideas of democracy and centralism are also intertwined with a theory of knowledge. In the stages of acquiring knowledge, an individual begins with perceptual or empirical knowledge gained through practical experience. Within the brain the individual then generalizes and formulates hypotheses or theories about such concrete data. The resulting rational knowledge is higher or more worthy than perceptual knowledge. Following this, individuals test their theories, observe and, if necessary, revise the theory. This process is

discussed in Mao’s essay ‘Shijianlun’. Chinese Marxists extended the analogy of the individual’s acquisition of knowledge to the mass line or to the leadership style required by democratic centralism. ‘From the masses’ consultation is analogous to sense perception by an individual; policy formulation at headquarters is analogous to theorizing in the brain; and testing/revising of theories is analogous to ‘to the masses’ teaching. Mao discusses this in several places, notably in ‘Guanyu lingdao fangfa di rogan wenti’ (Some Questions Concerning Methods of Leadership), written in 1943.

All of the above is compatible with the Leninist idea of elite officials knowing more than ordinary people. After all, they possess rational knowledge, which is higher than the perceptual knowledge of the masses. That possession justifies their privileges. The fusion of the mass line with a theory of knowledge also meets the demand of the doctrine of permanent revolution for the telescoping of progress through a historical stage. Leaders focus on transforming the minds or consciousness of the people as a way of rapidly modernizing the country socially and economically. Leaders are teachers who help transform the perceptual knowledge of the people into higher, rational knowledge. In consulting and then teaching, they satisfy the requirements of democracy and of centralism. Permanent revolution demands not only changing consciousness, it demands also the class struggle that follows in its wake. Other Marxists in China opposed the focus on struggle, advocating instead what they and their ideological opponents called ‘humanism’ (see §4).

After the communist victory in 1949 the consultative side of the mass line atrophied, but the leaders, members of the Communist Party, retained their instructional role. As during the imperial age, transforming the minds of the people remained a core function of officials. Among the many reasons why the consultative role evaporated was the increased difficulty of the task. Consulting in a small area such as the guerrilla bases was not difficult; consulting in a large country such as China was, especially when that country had no history of representative government. The difficult was ignored. Also, there were no built-in safeguards to the mass line consultation process; in gathering information, officials could easily filter out opinions or data they did not like. Finally, there was no institutionalized time period during which consultation had to be conducted.

As late as 1982, when China’s leaders issued a constitution, there was still no procedure for representative government. The constitution document is not a contract between leaders and people involving the sharing of power; it does more to protect the state from individuals than to grant inalienable rights to participate in government to the people. Nor does the constitution treat the individual as the best judge of the individual’s interests. Such an assumption is part of representative democracy and the obligation of leaders to consult with the people’s representatives.

4 Distributional equality versus material incentives

The content of the right ideas that should motivate people from socialism forward are in part summed up in the terms ‘class analysis’ and ‘class struggle’. However, there is another aspect, the priority of moral over material incentives. Like democracy, to which it is related, the principal Maoist thesis against significant wage differences took shape during the guerrilla period. Like democracy as mass line, its fate was affected by the switch from small societies in the guerrilla base areas during the 1930s and 1940s to its application to China in its entirety after 1949. The Maoist position was attacked intermittently by opponents during the next quarter-century, and finally evaporated after the death of Mao.

Marx himself had no special fondness for spreading wealth around equally, although popular writers often attribute such a concern to him. In *Critique of the Gotha Programme* (1875) he describes inequality of distribution as characterizing the first phase of communist society. Marx states that ‘The right of the producers is proportional to the labour they supply’. The essential trait of communism is not distribution but the elimination of the division of labour. Mao himself criticized those absolute egalitarians who would object to officers riding on horses in periods of guerrilla warfare. Officers have responsibilities and needs that justify some unequal material privileges.

However, Mao idealized the roughly egalitarian society of Yenan and the other base areas during the anti-Japanese war. He wrote that they had a free supply system (take what you need) and minimal contention. After 1949, he stated, the introduction of a differential wage system along with status differences increased quarrelling. In his ‘Reading notes on "The Soviet Union’s Political Economy"’, he wrote: ‘Right up to the early stages of liberation, people on the whole lived an egalitarian life. They worked hard and fought bravely on the battlefront. They

absolutely did not rely on material incentive for encouragement, but on revolutionary spirit'. After 1949, wage differences did continue to exist, but the gap was modest.

There is always the assumption that people can be self-motivating in pursuit of communist goals, especially those whose minds have been transformed. For the Maoist, this obviates the need for material incentives. In Maoist theory, however, social arrangements must coexist with transformed minds in order for this nonreliance on material incentives to prevail. There must be at least the illusion of democratic decision making and equality of status. Here is one place where the topics of democracy and egalitarianism converge.

Critics of this position included economists and some supreme leaders (for example, President Liu Shaoqi in 1962), who questioned its impact on productivity. The argument was that people who have an 'iron rice bowl' (guaranteed wage) have no motive to work harder or to innovate. A free supply system would not work in a large country because it requires an abundance of wealth that can only come later in the development process. Inherent difficulties in the policy of opposing material incentives included the fact that it was incompatible with two values to which its advocates were also committed: social order and self-sufficiency. Social order requires a chain of command and differences between those who give and those who take orders. Efficiency in maintaining order dictates status distinctions between them, often manifest in their access to different styles of uniform, to houses and cars that have different monetary worth, and so forth. With regard to self-sufficiency, if officials ask regions to prize self-sufficiency, they are also telling poor regions to be satisfied with what they have and not ask for handouts from wealthier ones.

The major departure from the Maoist position came after Deng Xiaoping assumed power in 1978. Economic reformers argued that socialist goals could best be attained by rejecting central government planning in favour of market factors such as price and profit. This meant taking profit into account in organizing and running an enterprise, wide differences in wages, legal protection of contracts between economic entities and toleration of individual entrepreneurs. Given China's clan-village social structure, individual entrepreneurs could be either individual persons or villages taking the initiative in starting industries, using village-owned resources. The existing village elites (Communist Party officials) would see their incomes rise most rapidly, along with the incomes of managers working on contract to the village.

5 Humanism and class struggle

Within the ranks of Chinese Marxists, the most serious challenge to Maoism in the 1950s and 1960s came from critics characterized as 'humanists'. After Mao's death in 1976, those Marxists who criticized the Communist Party were also humanists. Some of them decried the alienation of people from leaders caused by the party's dictatorship. Others participated in the growth of a new movement, 'subjectivism', that centred on the autonomy of all individuals as possible and desirable.

'Humanism' stood for opposition to Maoism in the 1950s and 1960s because it was a broad term under which a variety of perspectives could unite. First and foremost, it symbolized repudiation of the Maoist position that class struggle is the principal agent of historical change and the agent that could propel China into the modern world. The doctrine of class struggle assumes that human society is divided into distinctly different classes, that analysis of humans in class terms is the only correct sociological methodology and that class hatred is an inevitable motive in that struggle. In an essay from 1942 entitled 'Zai Yenan wenyi zuotanhui shangdi jianghua' ('Talks at the Yenan Forum on Art and Literature'), Mao had taken two positions that authorize such conclusions. One is that there is no pan-human or universal human nature common to all people. There are only the differing natures of people of different classes; within a given class, natures are somewhat uniform. The other is that love or sympathy that transcends classes is impossible; there is only love for members of one's own class. Class antagonism is therefore inevitable.

Both these positions are totally alien to the dominant Confucian legacy regarding the nature of humans and the ethical position that should flow from that assumption about human nature (see Confucian philosophy, Chinese; Xing). Together, these Confucian positions carry the label of 'humanism', although the term has several meanings in China. In attacking humanism, Maoists were simultaneously supporting class struggle and opposing the most powerful philosophical legacy of the past. This was the teachings of Mencius, who in the fourth century BC first formulated the concept of a universal human nature. The essential features of this universal nature are a mind that

evaluates right and wrong, and a sentiment of compassion. Mencius based an ethical and political position on this psychological analysis, namely that each person has an obligation to implement these features. Acting on the sense of compassion, individuals should extend their affection beyond family members and those who suffer to encompass an increasingly large number of other persons. Class-transcending love and universal traits set Mencius in opposition to Mao. Thus, to attack humanism was to attack the old, or that part of the old that was the greatest ideological threat.

In modern China, three disciplines have inherited the traditional concern with the topic of human nature: literature, philosophy and psychology. During the 1950s and 1960s, each of these was affected by the conflict between class struggle and humanism. In literature, Ba Ren (a pseudonym of Wang Renshu, a literary editor, critic and diplomat) got into trouble in the 1960s for insisting on the right of authors to deal with things that all people universally share, namely the love of the fragrance of flowers and the song of birds, and the desire to eat and to be warm. The popular philosopher Feng Ding of Beijing University was attacked for claiming that there is a survival instinct common to all persons. Beginning in 1958, younger Chinese psychologists shifted away from an interest in neurologically-based character types to focus on the subjective class standpoint or thought that separates people into social groups.

These themes dominated intellectual activity, in so far as it existed during the Cultural Revolution, until Mao's death. They were reinforced by rivalry with the USSR. The Soviet leader Nikita Khrushchev had claimed that the Soviet Union had eliminated class antagonism and was thus a 'state of all the people'. This sounded to Maoists like an arrogant claim that the Soviet Union had leapt ahead of China into communism, and that Soviet leaders were practising class-transcending love where class divisions actually still existed. This Chinese critique appears in an influential essay published in 1963 by Chou Yang (1908-), a leader of the All-China Federation of Literary and Art Circles and a member of the Department of Philosophy and Social Science of the Chinese Academy of Sciences. In this case, international political disputes had spilled over into philosophical debates.

6 Humanism and the end of alienation

With the death of Mao, some prominent Chinese Marxists shifted their concerns away from opposing class struggle towards promoting the free development of the individual. They treated these goals as humanistic goals. However, they shifted the content of humanism away from its Confucian focus on humaneness, being interested instead in the development of other, different human traits. Influenced by the early writings of Marx, long popular in eastern Europe, they spoke of the individual's freedom as the absence of alienation and described it positively as the all-round development of the individual.

This was a monumental leap in China. Mao had manifested no interest in the individual at all, only in classes or groups. His idea of ending the division of labour and promoting all-round development was sending intellectuals to the farm and introducing peasants to schools. This was intended to end the mental-manual division of labour, an ideal with some Marxist justification. However, Marx in his early works had a richer vision, one symbolized in some famous words of *The German Ideology* (1846) that describe a person who can metaphorically 'hunt in the morning, fish in the afternoon, rear cattle in the evening, criticize after dinner', without ever being simply one-sided. This was also the Renaissance humanistic ideal of the fully-developed individual human.

The ideals of the early Marx are also remarkably convergent with the ideals of nineteenth-century British liberals. Indeed, John Stuart Mill was influenced by the same German Romantics that influenced Marx. For those Romantics, the heroes were the artists who put into canvas or into stone their own personalities; they realize themselves in their art (see Goethe, J.W. von; Hölderlin, J.C.F.). These are also the heroes of Marx's *Economic and Philosophical Manuscripts* (1844). These manuscripts became popular with some Chinese Marxists because they directed attention away from class or group to individuals and their self-realization, thus providing the basis for an ethics in which individuals count for something. The *Manuscripts* do so by asserting that all people are born with basic needs (to realize themselves by means of variety in their lives and to be free agents in their productive work). However, most people are unable to satisfy those basic human needs. Marx described communism as humanism because in communism, all individuals are able to satisfy those needs and become fully human. To those Chinese Marxists who prized individual freedom, the contrast with the Maoist vision of communism could not have been more stark.

The most prominent of the advocates of this style of humanism after Mao's death was Wang Ruoshui, a former editor of the official newspaper *People's Daily* and one of the leading reform theorists. Wang accepted the premise (he never tried to prove it) that there are universal human needs, the most basic of which is for self-realization in an all-round, free manner. From this premise, he derived a standard to judge acts or policies. Good acts or policies foster the satisfaction of basic needs; bad ones cause individuals to feel alienated or separated from their natures. Wang used this standard to criticize the Communist Party's dictatorship. In his view, in the 1980s the Party fostered alienation in the Chinese people; individuals had little control over their work and bureaucrats constantly intruded into their lives.

The counterattack on this brand of Chinese Marxist humanism was mounted by Hu Qiaomu, one-time secretary to Mao, author of a history of the Chinese Communist Party and, towards the end of his life, honorary president of the Academy of Social Sciences. With the help of ghostwriters from the Academy's Institute of Philosophy, Hu produced an article entitled 'Guanyu rendaozhuyi ho yihua wenti' (On Humanism and Alienation), which appeared in the journal *Hongai (Red Flag)* in 1984. Hu's thesis was that it is acceptable to incorporate humanism into Chinese Marxism when the term stands simply for routine ethical considerations, such as being kind to an elderly or sick person, but it is not permissible to treat it as a theory of history or as something generating a serious standard. This, he claimed, is what people like Wang Ruoshui had done, by describing humanity's gradual evolution from alienation to need-satisfaction over time and deriving from this process the top normative standard. This is to treat humanism as a theory of history, said Hu, which is wrong. It leads to the impermissible conclusion that the Chinese Communist Party causes alienation, which cannot exist in socialism. The only correct theory of history is historical materialism, with its claims about stages of history, and the standard that one can draw from historical materialism tells whether or not a given policy is right as a function of its appropriateness for a particular stage or moment in history. In Hu's analysis, the dictatorship of the party passes this test as it is appropriate for China's current stage.

7 Subjectivity

The other current away from Maoism that permeated Chinese Marxist philosophy, literary criticism and psychology was subjectivity. In some versions, it too made a place for the individual's worth. Especially in this regard, subjectivity represents a break during the Deng era from the Maoist social class-centred analysis of human beings. It focuses instead on individuals having unique identities. When it began in 1978, the subjectivity movement was a radical departure from the implications of the term 'materialism' in historical materialism. It rejected the idea of humans as puppets whose consciousness is entirely formed by their socio-economic environment; specifically, it was a departure from the Leninist theory of reflection (the inner or mental is simply a reflection of the outer or environmental) that had dominated orthodox Leninist epistemology in China since 1949. Later, the subjectivity movement took two different directions.

Li Zehou, a Marxist philosopher from the Institute of Philosophy, took the lead among those who treated subjectivity as a new direction in epistemology. The objective world, they argued, is shaped by the subjective interests, interpretative paradigms or psychological memories unconsciously sedimented in human minds. The mind is active, not a passive reflector, and objectivity changes as subjects with different interests or (over time) differently sedimented memories come on the scene.

The other view of subjectivity flourished in literary and psychological circles. Here, subjectivity meant the ability and desirability of the individual acting autonomously. The literary critic Liu Zaifu of the Institute of Literature at the Academy of Social Sciences encouraged writers to portray in their works characters who act freely and are conscious of their autonomy. In psychology, this approach was seen as consistent with the worldwide movement away from Freudian psychological reductionism and behaviourism. The autonomous individual's inner needs and choices exist and count. These Marxists wished China to acquire the perspective of the European Enlightenment, wherein the beliefs of individuals do not need to be determined by gods, destiny or rulers. The individual can and should be in control. In working out these various positions on subjectivity, Chinese Marxists drew into their own heritage ideas from Immanuel Kant in the West and Wang Yangming in China.

Marxism, Western

Western Marxism is used here as an umbrella term for the various schools of Marxist thought that have flourished in Western Europe since Marx's death in 1883. It is sometimes used more narrowly to refer to those Marxist philosophers whose thinking was influenced by the Hegelian idea of dialectics and who focused their attention on the cultural as opposed to the economic aspects of capitalism. In the broader sense, Western Marxism does not denote any specific doctrine, but indicates a range of concerns that have exercised Marxist philosophers in advanced capitalist societies. These concerns primarily have been of three kinds: (1) epistemological - *what would justify the claim that Marxist social theory and, in particular, the materialist conception of history are true?; (2)*ethical - *does the Marxist critique of capitalism require ethical foundations, and if so, where are these to be discovered; and (3)* practical - *if the economic collapse of capitalism can no longer be regarded as inevitable, who are the agents who can be expected to carry through a socialist transformation?*

In relation to the first issue, the main debate has been between those who, following Engels, adhere to 'scientific socialism' (that is, the view that Marxism is a science in the same sense as the natural sciences), and those who claim that Marxist epistemology relies on a form of dialectics quite distinct from the methods of natural science. The most prominent exponent of this second view was the Hungarian philosopher Georg Lukács, who drew upon the dialectical method of Hegel, with class consciousness replacing Geist *(Spirit) as the vehicle of dialectical reason. Thus, for Lukács the truth of historical materialism and the goodness of communism were both established dialectically, through the class consciousness of the revolutionary proletariat. Lukács' advocacy of dialectics was later taken up and developed by the philosophers of the Frankfurt School.*

In relation to the second issue, early dissenters from the orthodox Marxism of Engels like Eduard Bernstein looked outside Marxism itself, and especially to the philosophy of Kant, for the ethical principles that would justify socialism. The position changed somewhat with the rediscovery of the young Marx's Paris Manuscripts *(1844) from which later Marxists, and in particular those associated with the Frankfurt School, were able to extract a humanistic ethics centred on the notion of alienation.*

In relation to the third issue, most Western Marxists continued to look to the proletariat as the agency of revolutionary change, often distinguishing, as did Lukács, between the true consciousness of that class and the false consciousness that reflected the distorting effects of bourgeois ideology. But in the case of the Frankfurt Marxists, the critical theory that pointed the way to a liberated human future was detached from any specific agency and treated merely as critique. The most original contribution was made by the Italian Marxist Antonio Gramsci, who argued that the working class must use the power of its ideas to establish hegemony over the other classes in bourgeois society, who would then join the proletariat in overthrowing capitalism.

The disintegration of Western Marxism began in the 1960s when the French philosopher Louis Althusser attacked both the use of Hegelian dialectics by Marxists and the various forms of Marxist humanism. Althusser insisted that Marxism was a science which required no ethical foundations. His critique was informed by a conviction that human subjectivity, together with the philosophical problems generated by subject-object dualism, are illusions.

Althusserian Marxism became fashionable in English-speaking universities, but its cavalier and paradoxical style also led, by reaction, to the rise of analytic Marxism in the late 1970s. Analytic Marxists returned to interrogating Marx's texts in more conventional ways, using the methods of analytic philosophy and contemporary social science to reformulate them to withstand academic scrutiny by non-Marxists. A tendency rather than a movement, analytic Marxism perhaps marks the final stage of a process that began with Lukács, that of turning Marxism into a purely academic study remote from politics.

1 Second International Marxism

Marx died in 1883 leaving his philosophical position unclear to his followers. His early philosophical writings were largely unpublished and unknown. He called his approach 'materialist' but it was not certain what this indicated beyond opposition to idealist philosophy and to religion, and a theory of history giving explanatory primacy to the production and reproduction of material life. His place was taken by Engels (§3), whose influence, until his death in 1891, was crucial for the way this uncertainty was resolved by the next generation of Marxist

theorists. Seldom philosophers, they were mostly politically engaged intellectuals involved in the rapidly growing working-class movements.

Engels considered Marx's economics a decisive scientific advance on classical political economy, and claimed that Marx did for history what Darwin had done for biological evolution. He believed these discoveries converged with those of natural science to demonstrate the truth of a dialectical and materialist ontology, and thought that epistemological and ethical questions could be resolved by scientific progress. Hence his description of Marxism as 'scientific socialism'.

Engels also tried to fill in the gaps in Marx's historical theory. He treated historical materialism as a causal theory, with causal interaction between 'base' and 'superstructure'. Development of the productive forces is determining only 'in the last instance'. He also added an 'ideological superstructure' to Marx's 'legal and political superstructure'. To keep scientific socialism from being ideological, he introduced the term 'false consciousness' (defined as a failure to see that the objective cause of supposed wants and ideals is class interest) and the notion that class interests, being the most powerful and uniform real motives, prevail in the long run by cancelling out short-term subjective motives. This was meant to explain why superstructures appear to be independent of, and neutral between, class interests when such is not the case, and why the scientific understanding of history differs from that of participants and chroniclers. But scientific socialism would enable the proletariat to pursue its class interest with the knowledge that its victory would then be inevitable, since it would coincide with the direction of material progress. Thus Engels pushed Marx's ideas rather naïvely towards a closed intellectual system.

Karl Kautsky, the leading theorist of Second International Marxism, interpreted Engels' philosophy in the light of the mixture of materialism, positivism and Darwinism popular among progressive German thinkers in the 1870s. Kautsky's outlook was highly determinist. He relied on the historical inevitability of capitalist crises and proletarian revolution for doctrinaire solutions to theoretical and political problems and failed to see that the inevitability of socialism supplied no moral argument for it. This determinism was allied to a cautious political strategy that welcomed trade unionism and parliamentarism as means of organizing the working class for the ultimate 'decisive hour', but denied that they could improve permanently the situation of the workers or prevent class polarization.

Kautsky's determinism was attacked by his revisionist colleague Eduard Bernstein. Bernstein, whose empiricism and 'evolutionary socialism' were influenced by the English Fabians, aimed to purge Marxism of revolutionary doctrine, which he blamed on the influence of Hegelian dialectics. He advocated a reformist strategy to achieve socialism legally and democratically. Stretching Engels' conception of causal interaction between base and superstructure, he argued that social evolution would give morality an increasing influence over production. He justified his moral position in terms of ethical universalism, in a neo-Kantian manner, denying that a practical doctrine like socialism can be scientific.

Orthodox Marxism was also criticized by sympathetic neo-Kantian philosophers dissatisfied with Engels' outdated materialism. Ethical socialists of the Marburg School, arguing that ethics cannot be based on anthropology, held that the Kantian principle that every human being ought to be treated as an end and not as a means prohibits workers being treated as commodities. Karl Vorländer saw Marx's theory of history and Kant's ethics as mutually complementary: the irreducible value of each individual implies worldwide human solidarity and justifies the connection between proletarian revolution and human emancipation.

The Kantian revival made its greatest impact on the Austro-Marxist school. In the early nineteenth century the leading intellectuals of the Austrian Social Democratic Party, Max Adler, Otto Bauer, Rudolf Hilferding and Karl Renner, shared an empiricist conception of scientific socialism as a system of sociology. Hilferding applied this perspective to economics, Renner to law and Bauer to politics. They shared a neo-Kantian commitment to ethical universalism while Adler supplied the epistemological foundations. Adler claimed, against the prevailing mechanistic interpretation of Engels' causal theory, that since all social phenomena are mental, social causality can be studied empirically only if Marx's concept of 'socialized humanity' is treated as a transcendental category of knowledge which is given a priori. Other Austrian Marxists, influenced by the neo-positivism of Mach and the Vienna Circle, opposed this Kantian Marxism.

Divergences within Marxism reflected new intellectual currents, national diversity and the pull of competing working-class ideologies. Thus Bernstein's revisionism was influenced by liberal reformism and Luxemburg's radicalism by syndicalism (see Luxemburg, R.). Syndicalism, an anarchist brand of trade-union militancy that took shape in France, became a revolutionary alternative to Marxism before the First World War, finding a champion in the unorthodox Marxist Georges Sorel who anticipated some later tendencies in Western Marxism.

Sorel rejected the notion of scientific socialism, together with most other rationalist *motifs* in Marxism, regarding Marx instead as a moralist like himself. He read *Das Kapital* (1867-) as a description of the corrupting economic system responsible for the decadence of bourgeois society and looked to working-class morality for its redemption. Becoming disillusioned with revisionism, he turned to syndicalism and direct action. For Sorel, class war was the central reality, and Marxism a 'myth' whose function was not to predict or guide but to inspire the workers to revolutionary industrial militancy. United and purified by violence, they would acquire the heroic moral qualities needed to destroy capitalism and found a new society of producers.

Meanwhile, Italian Marxism had also received a less orthodox stamp from the work of Antonio Labriola. An academic philosopher and anti-metaphysical Hegelian, Labriola's exposition of the materialist conception of history was opposed to inclusive, determinist and dogmatic interpretations, and his more open-minded approach, at once humanist and empirical, remained influential in Italy.

During this period the concept of ideology lost the negative connotation given to it by Marx and Engels as Marxists were forced to recognize the difference between science and morals. Bernstein argued that if all non scientific ideas are ideological, Marxism must be an ideology since it too is based on a moral ideal. Kautsky admitted the difference between scientific socialism and socialist ideals, but still distinguished the latter from 'bourgeois ideology' on the grounds that only these ideals now correspond with the needs of humanity. For Lenin, however, in exile in Switzerland, class struggle involved a straightforward conflict between bourgeois capitalist ideology and proletarian socialist ideology, whose outcome would be decided by history (see Ideology §1).

2 Western Marxism

Western Marxism in a narrower sense flourished between the Russian Revolution and the death of Stalin, an era of deepening division between Soviet communism and Western socialism. Its keynote was the claim that Marx was a dialectical philosopher in the Hegelian mould who had been misunderstood by Engels and Second International orthodoxy. It originated with Georg Lukács and Karl Korsch, philosophers who wrote after participating in failed revolutions in Hungary and Germany. In *History and Class Consciousness* (1921) Lukács argued that for Marx, as for Hegel, human history was a dynamic totality, an unfolding of reason which must be understood dialectically, and that this understanding is part of the process by which the whole is transformed. Its truth is available only to the historical agent - the proletariat - which becomes identical with the whole through the revolutionary action of consciously and deliberately transforming it. The proletariat is thus doubly privileged by history; by freeing itself it emancipates mankind from exploitation and it resolves the antinomies of philosophy in a transparent unity of theory and practice.

Lukács criticized empiricists and revisionists for isolating social facts from the whole since they can be understood and changed only by a total social transformation. Against Kantian and positivist Marxists he argued that the dualism of 'is' and 'ought' expresses a social separation of contemplation from practice that is overcome in the historical process, and so can be transcended in a dialectical understanding of history. By denying the scientific claims that were important to Marx and Engels, Lukács made the validity of Marxism depend on his own historicist conception of truth. This minimized the difference between social science and ideology; both are expressions of the 'reified consciousness' of the bourgeoisie and reflect the reified social relations of the market to which economics gives an illusory objectivity. There are no 'laws of dialectic' which science proves, as Engels maintained, nor laws of history external to the consciousness of the proletariat. Historical materialism is a critical-revolutionary method, exemplified by Marx's critique of bourgeois political economy or Lukács' own critique of bourgeois philosophy.

But Lukács also warned that the workers, as the 'identical subject-object of history', could only escape reification and false consciousness if enlightened by Marxist leadership. He eventually interpreted this theory of class consciousness in Leninist terms, and reconciled himself to Stalinism as a lesser evil than capitalism. Thus his ideas

had both a critical and an orthodox face, the latter increasingly predominant.

It was their critical aspect that inspired the ’critical theory’ of the Frankfurt School. The Frankfurt Institute of Social Research was established in 1923. Its central figures, active in Germany or the USA for the next forty years, were Max Horkheimer, Theodor Wiesengrund Adorno and Herbert Marcuse. Primarily philosophers, scholars at the Institute none the less developed new Marxist approaches to economics, politics and literature. Erich Fromm, a founder of the culturalist school of psychoanalysis, was also a member (see Frankfurt School).

Frankfurt Marxists were radical in thinking modern civilization diseased beyond hope of reform. They believed in the possibility of a utopian future, but not in a proletarian revolution, and had no political programme. Since they shared Lukács’ belief in the philosophical self-sufficiency of dialectics, their utopianism had to supply the dialectical premises, both epistemological and ethical, for their otherwise antifoundational critical stance. This was directed at both capitalism and Soviet state socialism, as well as at fascism, liberalism and all varieties of ’bourgeois’ philosophy, especially positivism and existentialism (see Critical theory).

Treating Marxism as method rather than theory, they drew on psychoanalysis to explain the sources and mass appeal of authoritarianism and extended Max Weber’s critique of bureaucracy. They emphasized the increasing integration of state and economy (’state capitalism’) and the replacement of traditional ideology with standardized escapist products of the modern ’culture industry’. They carried to implausible extremes the idea that Enlightenment rationalism had culminated in the fetishization of science and technology, which eroded human values and led to a conservative, totalitarian manipulation of a dehumanized society in the name of ’instrumental reason’. This was contrasted, in Hegelian fashion, with dialectical reason, but Adorno’s insistence on critical independence from all absolutes plunged his version of ’negative dialectic’ into obscurity and irrationalism. Although Frankfurt Marxists were mostly pessimistic, Marcuse and Fromm criticized Freud’s pessimism from the standpoint of Marx’s theory of alienation and took a more optimistic view of the possibilities for human enjoyment, creativity and community, appealing to essentialist beliefs about human nature (see Alienation §§3-5).

These German developments were paralleled by the reflections of the Italian Communist Antonio Gramsci during his ten years in a fascist jail. Gramsci had imbibed a neo-idealist critique of positivism from Croce (§4) and emphasized dialectical interaction between base and superstructure to a point where the concepts lost any precise meaning. Rejecting orthodox scientific socialism more radically than Labriola, and relying on Marx’s *Theses on Feuerbach* (1845), he treated Marxism as a historicist philosophy of human praxis, in which thought is a socially conditioned activity and truth is relative to its historical function. Belief in historical laws, he argued, was merely a necessary illusion of the proletariat in its early struggles, an idea close to Sorel’s view of Marxism as myth.

Gramsci’s contribution to the study of ideology was his theory of hegemony. In addition to exercising domination through the coercive apparatus of the state, ruling classes seek hegemony (leadership) through control of the cultural institutions of ’civil society’ - churches, schools, mass media and so on - and are stable only if they rule by consent. Since modern civil society is highly developed, the working class can introduce socialism only by achieving hegemony *before* seizing the state. Each class needs ’organic intellectuals’ to articulate its values, but the weakness of the workers in this respect had left them ’passively consenting’ to bourgeois values, although their actual behaviour showed this to be a type of false consciousness. Gramsci was a major source for the ‘dominant ideology thesis’ and has been criticized for exaggerating the role of ideas.

The strength of socialists and communists in France after 1945 encouraged fellow-travelling by *marxisant* philosophers. This coincided with a vogue for Hegel, the recent availability of Marx’s *Paris Manuscripts*, and a new interest in existentialism and phenomenology. The hybrid Marxism of Jean-Paul Sartre (§5), Maurice Merleau-Ponty and others was the result. For Sartre, Marxism meant historical materialism and class struggle, stripped of naturalistic justifications, and the philosophical task was to ground these existentially in individual praxis. He explained alienation by scarcity; subjective freedom is lost through the historical struggle to produce, resulting in the reified social objectivity of the ’practico-inert’ - a view more Hegelian than Marxian. This condemns individuals to ’serial’ consciousness from which they can be liberated only by the collective consciousness of the ’fused group’. Hence a Sorelian justification of violence for the sake of moral authenticity and, even more questionably, support for Stalinism as a radical denial of bourgeois objectivity (see Violence).

Like Sartre, Merleau-Ponty explicated Marx through Hegel’s dialectic of master and slave. At first, like Lukács, he defended Soviet totalitarianism as a lesser evil, which might in time produce a society without wage slaves. But after Stalin’s death he turned to social democracy and attacked Sartre’s combination of existentialism and Bolshevism. French Marxists of this period affiliated to the Frankfurt School or Lukács rather than existentialism were Henri Lefebvre and Lucien Goldmann.

Leon Trotsky, exiled from Russia in 1919, became an involuntary contributor to Western Marxism. His political analyses were influential, although a book on Marxist ethics made little impact. Together with Western Marxism, Trotskyism contributed to the New Left movement, which arose in English-speaking democracies in reaction to the Cold War. Marcuse’s *One-Dimensional Man* (1964) popularized a sub-Marxist analysis of late capitalism as a technocratic, consumerist totalitarianism. He endorsed militant students, racial minorities and Third World insurgents as the new agents of liberation. A side effect of the New Left was to promote research on subjects relevant to Marxism, and as Western Marxism penetrated east European universities it stimulated new critical studies there also.

3 The disintegration of Western Marxism

The French Communist philosopher Louis Althusser launched his structuralist alternative to dialectical Marxism in 1965 with the publication of his book, *Pour Marx*. It promised a scientific rehabilitation and modernization of Marx, drawing on a new theory of discontinuities in the history of science. Althusser claimed to detect an ’epistemological break’ between the humanist and historicist ideology of Marx’s youth, based on the ’problematic of the subject’, and the science of his maturity, which described a ’history without subjects’. Psychoanalysis suggested a ’symptomatic reading’ of *Das Kapital*, to extract the outlines of the new science, while structural linguistics provided a model for the resulting reinterpretation of historical materialism. This now became an ahistorical theory of ’structures in dominance’, exercising a ’structural causality’ whose effects are borne by human agents. In reality this was a kind of sociological functionalism. Gramsci’s theory of hegemony was stretched to make ideology the universal social cement that reproduces social structures, even under communism, by giving individuals an illusion of free agency. The truth of these theories was treated in a question-begging manner, as an effect of theoretical structures that are scientific and not ideological. Althusser’s approach, implausible as a reading of Marx, reflected a French philosophical interest in deconstruction of the subject which survived the eclipse of his school and the decline of French Marxism (see Structuralism).

Italian Marxism showed a parallel shift away from Hegelian Marxism, but in a different direction. Galvano della Volpe and Lucio Colletti reacted against the historicist aspects of Gramsci’s Marxism in favour of more empiricist readings of Marx. This has led Colletti to reject dialectics and the theory of alienation and, finally, socialism - one example among many of ’post-Marxism’.

Elsewhere, Althusserian Marxism was bypassed by more eclectic theorists who maintained that a critique of modern society drawing on Marx’s values could no longer be merely ’Marxist’. In Germany Jürgen Habermas transformed critical theory by supplementing Marx with theoretical perspectives drawn from sociology, linguistic philosophy and hermeneutics. He criticized Marx for viewing history and human emancipation reductively, in terms of labour, and claimed that interaction, involving communication and social norms, is an independent dimension of social life. A human interest in emancipation is the constitutive ground of the social sciences, whose method is critical because they are implicitly oriented to an ’ideal speech situation’. Their truth, like other human values, is a function of dialogue freed from ideological distortion by the equal participation of all. Habermas’ critics, however, deny that he can demonstrate that free dialogue on equal terms presupposes consensus on values.

Analytic Marxism developed in English-speaking countries in the late 1970s and 1980s, partly as a reaction of academic socialists to Althusserian excesses. It is characterized more by respect for traditional canons of argumentation than by theoretical or political consensus. G.A. Cohen’s cogent demonstration that Marx intended historical materialism to be a functional theory challenges both the causal (Engels) and dialectical (Lukács) interpretation. He defended Marx’s functional explanations in a debate with Jon Elster, for whom functional statements are no more explanatory than dialectics. Elster’s own contributions include a recasting of Marx’s class theory in rational choice terms, and a psychological approach to the explanation of ideology. Other writers have sought to present Marx’s epistemology as a form of scientific realism.

Analytic Marxists were responding in part to the resurgence of economic and political liberalism in the 1980s. This shows in their concern to make Marx's theory of exploitation independent of his discredited economics and, more generally, in a wish to reinstate individuals in Marx's thought - both methodologically, as providing microfoundations for historical explanations, and normatively, as intended beneficiaries of a communist utopia. Hence another debate, this time over whether Marx had, or ought to have had, a theory of justice, and whether it could be consistent with his theory of ideology. Radical critics see analytic Marxists as engaged in a bourgeois academic pastime. But they can also be seen as conservationists, preserving the valid residue of Marxism for a post-Marxian world.

Marxist philosophy of science

Marx's approach to science is an intriguing combination of respect for the natural sciences and empirical inquiry, determination to go beyond the description of regularities among observable phenomena, and insistence on the inevitable impact of social circumstances on scientific inquiry. Marx thought that the human sciences and the natural sciences are governed by essentially the same methods, that natural-scientific theories give us enhanced insight into mind-independent reality, and that our most fundamental views are subject to revision through scientific inquiry. Yet Marx rejected the ideal of scientific method according to which rational scientific belief is tied to observational data through a canon of rules as general, timeless and complete as the rules of logical deduction. While traditional empiricists emphasize the economical description of empirical regularities which could, in principle, be used to predict the occurrence of observable phenomena, Marx emphasizes the description of underlying causal structures, employing concepts that are typically irreducible to the vocabulary of mere observation, and causal hypotheses that sometimes do not even sketch means of prediction. Similarly, though Marx shared the optimistic view that science gives rise to long-term improvement in our insight into underlying causes, he disagreed with many epistemic optimists in his insistence that scientific inquiry is inevitably and deeply affected by social interests and relations of social power.

Since Marx's general comments on scientific method are few and scattered, a 'Marxist philosophy of science' consists of the further development of this intriguing mixture.

1 Explanation and theory in Marx

Marx's social theorizing has been attacked as a muddled perversion of science, lacking adequate predictive power and insufficiently connected with empirical data. Consider Marx's materialist conception of history: any stable society's political and cultural institutions have their most important features because their having them serves to maintain the dominant relations of production (the relations of control that dominate material production); an internally-caused change in a society's dominant relations of production is due to processes within the mode of production (the relations of production, work relations and technology) which create desires and powers destroying the old system of relations of production. Marx was well aware that similar networks of relations of production have been stabilized by importantly different political and cultural institutions. He acknowledged that one process (for example, the formation of a proletariat under capitalism) may ultimately doom a social system while a similar process (for example, the formation of the Roman proletariat) has no transformative effect. In a poignant letter to Russian activists who sought his guidance, Marx denied that his general theory provides any 'master key' permitting one to distinguish transformative from non-transformative processes without knowing their outcomes. So all that is rational in his general theory of social change might seem to be trivial: a tautology, that basic change occurs when changes in the mode of production are powerful enough to produce them, together with a banality, that there are important changes within the mode of production in the period leading up to a fundamental change in society as a whole.

A Marxist philosophy of science counters with an alternative view of science. A theory provides a description (sometimes a vague one) of a repertoire of underlying mechanisms, and says that the instantiation of these mechanisms has a certain importance as the cause of certain phenomena. A theory is confirmed by showing that such reliance on its repertoire does a better job than reliance on rival theories of explaining phenomena that stand in need of explanation. Such an argument will partly consist of the explanation of particular phenomena, especially those that have posed long-standing problems for prior explanatory schemes. It will also depend on more general inferences, resting on shared background principles, as to the possible causes of the general kind of phenomenon in question - for example, Marx's arguments that stabilizing tendencies of cultural and political institutions will prevent basic change arising from parts of a social system that are outside the mode of production.

A theory that triumphs in this way need not be useful as a basis for prediction. Marx, of course, *was* committed to certain long-term predictions, but (in this controversial view of Marx which implies a distinctive philosophy of science) these predictions are based on his specific account of capitalism. For Marx, the essence of confirmation is the critical comparison of theories (as Althusser has emphasized), in which the empirical data to be explained are one crucial lever of comparison (which Althusser has been charged with neglecting).

The development of auxiliary hypotheses connecting the general mechanisms in the basic repertoire with relevant concrete phenomena may be an extremely demanding task. In remarks on his economics of capitalism which sometimes liken it to Daltonian chemistry, Marx emphasizes the distance between the processes of class struggle and technological change which he describes using the vocabulary of the labour theory of value, and the economic facts which the underlying processes help to explain, facts which are to be described in the vocabulary of commerce. Although he takes the former processes to be real and fundamental, he thinks they never produce their effects without the mediation of other, market-based processes, the topics of the second and third volumes of *Capital*. Nowak (1980) takes this process of abstraction from, followed by reconstruction of, concrete phenomena to be the essence of Marx's scientific method.

2 Holism

Marx has also frequently been charged with assuming an implausible dominance of social wholes over individual parts in which large-scale social processes have obscure powers to manipulate individual participants (see Holism and individualism in history and social science). Thus, the goals of Cromwell and his followers were mainly religious and political concerns, not concerns to end the feudal restriction of emergent capitalist forces of production. Yet Marx takes the English Revolution to inaugurate the transformation of England into a capitalist society, a transformation he explains as serving to overcome feudal barriers to expansive capitalist production.

Part of Marx's implicit answer to the charge of arcane manipulation is a distinction between explanatory adequacy and causal sufficiency. Marx's historical writings consist largely of the richly detailed description of networks of individualist causes, actions governed by the reasons and resources of individual participants. Yet he thinks such individualistic description lacks the depth needed to explain major social transformations: the transformation would have occurred anyway. Thus, if the political, religious and military events that led to the Commonwealth, the Stuart Restoration and the Glorious Revolution had not transpired, a modernizing, bureaucratic state, advancing the interests of enterprising gentry and manufacturers, would have arisen anyway, on account of prior trends within the mode of production.

Still, the social outcome will result from some network or other of individualist causes. How can large-scale functional characteristics such as the expansive needs of capitalist production regulate these individualist causes when the satisfaction of these functions is not a typical dominant reason for which participants act? Here, Marx is psychologically ingenious in a way that breaks down rigid separations of the structural from the individual. He thinks that the history of ideas (for example, the history of religious differences in seventeenth-century England) establishes the enormous importance of mechanisms moulding belief or desire that do not consist of the subject's reasons for belief or desire. For example, he emphasizes the tendency of beliefs and goals to adjust to material interests, even among those who would accurately deny that these interests are their reasons for believing and desiring as they do. In his favoured explanatory scheme, rational choices within the mode of production have unintended consequences, transforming the pattern of resources and material interests (most importantly, by creating an interest in the destruction of inhibiting social forms on the part of a newly powerful economic class); then, consequent adjustments of goals and beliefs give rise to new psychologies that are the vehicle of social change. Thus Marx's project of explaining large-scale phenomena is also the basis for a novel view of the mechanisms of change in individual participants.

3 Materialism and dialectics

Marx takes both the social and the natural sciences to vindicate a materialist, dialectical view of reality. In its broadest claim, Marx's materialism has it that everything that exists is made of matter and is governed by the causal powers that physics seeks to discover. However, his materialism is not reductive. Within the constraints that the laws of physics impose, other laws regulate phenomena, in ways that cannot be described in the vocabulary of physics (see Dialectical materialism; Reduction, problems of; Unity of science).

Marx's view of cognition is also materialist in that it gives priority to material interests and mind-independent causes. Cognition grows out of the effort to change reality in order to satisfy one's needs. Initially, our concepts mark as relevant the distinctions that are practically important to us. The frustration of our efforts and expectations, together with the social exchange of information which is our main resource for effective change, lead to the continual revision of beliefs and even of the concepts in which they are framed. Like those modern

‘scientific realists’ who emphasize the success of theory-dependent interventions, Marx took the question of whether the whole process of inquiry improves the truth of our beliefs to be settled by its contribution to our capacity to get our way with nature (see Realism and antirealism).

The dialectical side of Marx’s outlook, which reconstructs Hegel’s logic on a materialist basis, was presented much more systematically by his co-worker Engels. In this dynamic view, every part of total reality is at once an active source and a passive object of change and no part is completely distinguishable from the rest. It is of the nature of everything to change from internal causes, because what stabilizes anything is a temporary balance of polar opposites whose conflict dictates transformation and, eventually, self-destruction. (Two alleged examples are the antagonistic relation between the proletariat and the bourgeoisie that characterizes capitalism and the balance of attraction and repulsion in a physical object.) Engels also emphasizes the tendency, in appropriate circumstances, for quantitative changes to become qualitative (for example, when water becomes ice, or a rural English bourgeoisie emerged from the growing prosperity of the better-off Tudor farmers) and the prevalence of spiralling processes of change in which an initial transformation is followed by another that restores aspects of the first stage (the ’negation of the negation’.)

There is much banality and word-juggling in Engels’ illustrations of these principles. But there is also much shrewdness and wide-ranging scientific erudition in his criticism of opposed ‘mechanistic’ approaches, which analyse systems as arrangements of passive, simple, unchanging elements.

4 Objectivity and society

If cultural institutions tend to serve the interests of economically dominant classes, then explanatory frameworks will often be favoured on account of processes with no tendency to produce truth. If cognition grows out of the effort to satisfy human needs in a largely purposeless world, then our ways of characterizing causes will probably always misrepresent nature’s actual causal repertoire. Marx and Engels certainly take scientific inquiry to be subject to these limits. Thus, Marx associates the rise of a politically assertive working class in mid-nineteenth-century Britain with the retreat from hypotheses of conflicting class interests among established economic theorists, while Engels takes reluctance to countenance the evolution of species and celestial bodies to reflect commitment to the fixity of the social order. And both emphasize that any science is bound to misdescribe its subject matter in important ways.

However, mainstream Marxist thinking asserts that scientific inquiry has yielded rational truth claims of broader and broader scope. Outside of a few platitudes, the most that we can rationally claim is that a hypothesis is true within a certain limited sphere, or true enough for certain purposes, or capable of correctly resolving the current controversies with the most important bearing on scientific progress. But (as Lenin put it, in criticizing what would now be called ‘social constructivist’ philosophies of science) it is often rational to claim access to objective truths of this relative kind.

Scientific inquiry is, inevitably, social, and social processes are inevitably affected by social interests in ways of which the participants are not fully aware. Still, in Marx’s view, the impact of social interests does not always distort truth or rationality. For example, he takes the process of increasingly collective resistance which gave rise to class-conscious workers’ movements to be interest-driven*and* to have enhanced truth and rationality in theorizing allied with those movements. Nor is the pressure of social interests intellectually decisive, for him, all the time - as witness his respect for the achievements of the quite bourgeois economists of late eighteenth- and early nineteenth-century Britain.

Even if Marx’s frequent attributions of religious, political and moral trends to truth-distorting social forces are not preliminaries to an anti-objectivist philosophy of science, they might be extended into the social history of philosophies of science and allied epistemologies themselves. For example, Lenin (1908) argues that the currency of Mach’s radical empiricism is partly due to its appeal to those who seek to preserve room for escape into religious wishful thinking: if the most that theoretical science can do is to organize experience in satisfying ways, then religion does as well for the devout.

Lukács’ essay, ‘Reification and the Consciousness of the Proletariat’, is perhaps the most wide-ranging project of this kind. He traces the dilemmas of modern epistemology to the psychopathology of life in a market-dominated society. Routine dependence on labour-markets in which impersonal forces determine the monetary value of the

use of one's labour-power leads people to separate their activities into an immediately experienced subjective sphere and an impersonal objective sphere and to question whether the subjective can reflect objective facts. Market-dominance also gives rise to a formal, calculative conception of rationality, on which people rely to re-establish objective validity. But this reliance only makes the problem more acute, since rationality based on formal principles gives no significance to the content of experience. Lukács subsequently abandoned this approach, on the ground that it treated the real difference between the subjective and the objective as an artefact of ideology, but it has had an extensive influence on subsequent Continental criticisms of positivist philosophy of science, the main twentieth-century legacy of traditional empiricism.

Arguments that presuppose the truth of Marxist social theory have never been important in Anglo-American philosophy of science, and are now virtually extinct. But the larger attitudes toward science of Marx and his successors are very much alive in the search for a replacement for positivism that has dominated philosophy of science since the 1950s. For those who emphasize both the reality of theoretical posits and the need to connect them with observations, the inadequacy of canons of induction and the genuine limits of rational disagreement, the autonomy of large-scale structures and the importance of their micro-constitution, the objective validity of inquiry and its dominance by human interests, the Marxist tradition is as much a home as any and a richer source of inspiration than most.

Marxist philosophy, Russian and Soviet

The history of Russian Marxism involves a dramatic interplay of philosophy and politics. Though Marx's ideas were taken up selectively by Russian populists in the 1870s, the first thoroughgoing Russian Marxist was G.V. Plekhanov, whose vision of philosophy became the orthodoxy among Russian communists. Inspired by Engels, Plekhanov argued that Marxist philosophy is a form of 'dialectical materialism' (Plekhanov's coinage). Following Hegel, Marxism focuses on phenomena in their interaction and development, which it explains by appeal to dialectical principles (for instance, the law of the transformation of quantity into quality). Unlike Hegel's idealism, however, Marxism explains all phenomena in material terms (for Marxists, the 'material' includes economic forces and relations). Dialectical materialism was argued to be the basis of Marx's vision of history according to which historical development is the outcome of changes in the force of production.

In 1903, Plekhanov's orthodoxy was challenged by a significant revisionist school: Russian empiriocriticism. Inspired by Mach's positivism, A.A. Bogdanov and others argued that reality is socially organized experience, a view they took to suit Marx's insistence that objects be understood in their relation to human activity. *Empiriocriticism was associated with the Bolsheviks until 1909, when Lenin moved to condemn Bogdanov's position as a species of idealism repugnant to both Marxism and common sense. Lenin endorsed dialectical materialism, which thereafter was deemed the philosophical worldview of the Bolsheviks.*

After the Revolution of 1917, Soviet philosophers were soon divided in a bitter controversy between 'mechanists' and 'dialecticians'. The former argued that philosophy must be subordinate to science. In contrast, the Hegelian 'dialecticians', led by A.M. Deborin, insisted that philosophy is needed to explain the very possibility of scientific knowledge. The debate was soon deadlocked, and in 1929 the dialecticians used their institutional might to condemn mechanism as a heresy. The following year, the dialecticians were themselves routed by a group of young activists sponsored by Communist Party. Denouncing Deborin and his followers as 'Menshevizing idealists', they proclaimed that Marxist philosophy had now entered its 'Leninist stage' and invoked Lenin's idea of the partiinost' *('partyness') of philosophy to license the criticism of theories on entirely political grounds. Philosophy became a weapon in the class war.*

In 1938, Marxist-Leninist philosophy was simplistically codified in the fourth chapter of the Istoriia kommunisticheskoi partii sovetskogo soiuza (Bol'sheviki). Kraatkii kurs (History of the Communist Party of the Soviet Union (Bolsheviks). Short Course). The chapter, apparently written by Stalin himself, was declared the height of wisdom, and Soviet philosophers dared not transcend its limited horizons. The 'new philosophical leadership' devoted itself to glorifying the Party and its General Secretary. The ideological climate grew even worse in the post-war years when A.A. Zhdanov's campaign against 'cosmopolitanism' created a wave of Russian chauvinism in which scholars sympathetic to Western thought were persecuted. The Party also meddled in scientific, sponsoring T.D. Lysenko's bogus genetics, while encouraging criticism of quantum mechanics, relativity theory and cybernetics as inconsistent with dialectical materialism.

The Khrushchev 'thaw' brought a renaissance in Soviet Marxism, when a new generation of young philosophers began a critical re-reading of Marx's texts. Marx's so-called 'method of ascent from the abstract to the concrete' was developed, by E.V. Il'enkov and others, into an anti-empiricist epistemology. There were also important studies of consciousness and 'the ideal' by Il'enkov and M.K. Mamardashvili, the former propounding a vision of the social origins of the mind that recalls the cultural-historical psychology developed by L.S. Vygotskii in the 1930s.

However, the thaw was short-lived. The philosophical establishment, still populated by the Stalinist old guard, continued to exercise a stifling influence. Although the late 1960s and 1970s saw heartfelt debates in many areas, particularly about the biological basis of the mind and the nature of value (moral philosophy had been hitherto neglected), the energy of the early 1960s was lacking. Marxism-Leninism still dictated the terms of debate and knowledge of Western philosophers remained relatively limited.

In the mid-1980s, Gorbachev's reforms initiated significant changes. Marxism-Leninism was no longer a required subject in all institutions of higher education; indeed, the term was soon dropped altogether. Discussions of democracy and the rule of law were conducted in the journals, and writings by Western and Russian émigré

philosophers were published. Influential philosophers such as I.T. Frolov, then editor of Pravda, called for a renewal of humanistic Marxism. The reforms, however, came too late. The numerous discussions of the fate of Marxism at this time reveal an intellectual culture in crisis. While many maintained that Marx's theories were not responsible for the failings of the USSR, others declared the bankruptcy of Marxist ideas and called for an end to the Russian Marxist tradition. Following the collapse of the Soviet Union in 1991, it seems their wish has been fulfilled.

1 The beginnings of Russian Marxism

It is not surprising that Marxism captured the imagination of the radical Russian intelligentsia in the late nineteenth century. Questions of social justice, so pressing in Tsarist Russia, dominated philosophical debate. Marxism, a putatively scientific theory of history that promised humanity's self-realization through the liberation of the oppressed masses, appealed to Russian thinkers, preoccupied with human destiny and Russia's role within it, and anxious for a vision that would unite theory and practice. The story of the subsequent domination of Russian philosophy by Marxism is more remarkable, involving a dramatic interplay of philosophy and politics. On the one hand, the Bolshevik project was inspired and guided by a philosophical doctrine; on the other, it resulted in the almost total subordination of philosophical enquiry to political power.

Russian radicals in the 1870s were acutely aware that Marx's theories were written for the industrial nations of Western Europe, not a quasi-feudal autocracy like Russia with a largely peasant economy (*Capital* was published in a Russian translation in 1872). Thus Marxist ideas were at first adopted selectively. The Russian populists, whose leading thinkers were P.L. Lavrov (1823-1900) and N.K. Mikhailovskii (1842-1904), invoked Marx's economic theory in their critique of the horrors of capitalism, but argued that Russia could avoid capitalism altogether by adopting directly a form of communism based on the peasant commune.

The populists differed on how this transformation was to be achieved. While some insisted the masses must engineer their own emancipation, others, like Pëtr Tkachëv (1844-86 NS), favoured a revolution led by a centralized party of conspirators. It was the adventurism of this latter group that pushed some in the populist movement towards a more comprehensive Marxism. Georgii Plekhanov (1856-1918) argued that the socioeconomic forces at work in Russia in fact conformed to Marx's theory of history: capitalism was indeed developing apace and could not be sidestepped. But the admission that capitalism was the unavoidable precondition of a socialist future raised a moral problem. How could revolutionaries endorse the coming of capitalism, when it would bring misery to the masses they sought to liberate? Plekhanov argued that it was futile to resist the inevitable on moral grounds. However, Marxists need not sit idly by; they must awaken the proletariat's self-consciousness. Plekhanov also maintained, percipiently, that the imposition of socialism would result in a 'patriarchal and authoritarian' communism, worse than enduring the evils of capitalism.

Plekhanov sought to justify his economic determinism by placing it in a broader materialist vision, and in *K voprosu o razvitii monisticheskogo vzgliada na istoriiu (The Development of the Monist View of History)* (1895) he articulates a conception of philosophy that came to dominate Russian Marxism. Inspired by Engels, Plekhanov argues that the history of philosophy is a battle between materialism and idealism. The former aspires to explain everything in material terms, the latter in terms of spirit or idea. (Like most Russian thinkers, Plekhanov is profoundly attracted to *monistic* positions; he simply dismisses dualism as unable to explain how its two explanatory principles - matter and spirit - are related (see Dualism).) Endorsing materialism, Plekhanov praises the French thinkers of the eighteenth and nineteenth centuries, especially Helvétius, for holding that ideas are determined by the social environment. These thinkers, however, mistakenly portray human history as the outcome of ideas ('opinions govern the world') or a reflection of an unchanging human nature. Paradoxically, a more plausible materialism was made possible by Hegel's dialectical idealism. In contrast to static, metaphysical conceptions of reality, Hegel stressed that phenomena are interconnected and constantly changing. He saw that gradual, quantitative changes in phenomena eventually result in their abrupt qualitative transformations, that every phenomenon is eventually transformed into its opposite, and that contradiction is the motor of development. Hegel, however, also misunderstood history, representing it as a manifestation of the 'world spirit' (see Hegel, G.W.F.). The genius of Marx and Engels was to invent a form of dialectical materialism (see Dialectical materialism). Their view is materialist because it represents cultural, social, economic, legal, political and ideological relations (the superstructure) as ultimately determined by the level of development of material forces of production (the

economic base). It is dialectical in its dynamic vision of history. Human beings, acting collectively and with the use of tools, are able to change their environment so radically that this in turn transforms their own nature. However, as the level of productive forces increases and human beings master the natural world, they become ever more enslaved to economic forces unleashed by their activity. Marx's theory of history reveals the true character of those forces and how they will be mastered with the emergence of communism. The proletarian revolution represents a transition from the realm of necessity to the realm of freedom. Human beings will no longer labour under alien powers, but will be able knowingly to conform their actions to the dictates of necessity.

2 Orthodoxy and revision before 1917

Though Plekhanov's dialectical materialism quickly became orthodoxy, it struck many as unsatisfactory, for his determinism seemed to preclude human agency and moral criticism. The school of legal Marxists, so called because its representatives published legally under their own names, responded to this failing. These thinkers, led by Pëtr Struve (1870-1944), endorsed Marx's economic theory as proof that Russian absolutism was doomed by the inevitable development of capitalism (which, in contrast to the populists, they saw as a progressive force). They argued, however, that Marxism could not inspire moral renewal unless supplemented with a broader philosophical and ethical perspective. To this end, the legal Marxists turned to Kant (anticipating Eduard Bernstein). The resulting synthesis was fragile, and in 1900 most legal Marxists migrated from social democracy to form the basis of the liberal Constitutional Democratic Party. Struve, N.A. Berdiaev (1874-1948), S.N. Bulgakov (1871-1944) and S.L. Frank (1877-1950) eventually embraced an idealism based on Russian religious thought, which they presented in the symposium *Vekhi (Signposts)* in 1909, provoking a scornful attack by Lenin (see Signposts movement).

Another significant revisionist view was the attempt, by A.A. Bogdanov (1873-1928), A.V. Lunacharskii (1875-1933) and others, to reconcile Marxism with the empiriocriticism of Ernst Mach and Richard Avenarius. The Russian empiriocritics were drawn to Mach's positivist view of science, seeing it not as describing reality beyond appearance, but as providing progressively better ways of organizing experience. Scientific laws do not pick out real necessities in nature, but read order into the deliverances of the senses. The Russians supplemented Mach's neo-Darwinist epistemology with the view that reality is *socially* organized experience, taking this to fit Marx's view in the *Theses on Feuerbach* that objects should be conceived 'as sensuous human activity' (see Russian empiriocriticism).

Bogdanov's *Ėmpiromonizm* (1905-6) maintains that the very dichotomy between materialism and idealism is confused. The mental-physical distinction does not pick out two kinds of entity or substance. It is rather a distinction drawn within experience. Some elements of experience are deemed 'mental' because they are given only to one subject; others are called 'physical' because given to many. Bogdanov argued that under communism, where disagreement and conflict are eradicated, people will share the same modes of organizing experience and the idea of individuals as separate mental worlds will break down. Other consequences of the theory were less extravagant. Bogdanov's interest in organization led him to develop tektology, a precursor of cybernetics and general systems theory.

In 1902, the Russian Social Democratic Party split into two factions. The Bolsheviks embraced the conception of the vanguard party set out in Lenin's *Chto delat' (What Is To Be Done?)* (1902), a centralized and disciplined organization of professional revolutionaries (reminiscent of Tkachëv's view). In contrast, the Mensheviks advocated a broad party embracing many kinds of proletarian support. This conflict reflected different conceptions of revolution. While the Bolsheviks saw revolution as something to be engineered, the Mensheviks awaited a spontaneous uprising precipitated by social forces beyond immediate control.

Although there were empiriocriticists in both factions, the philosophy was associated with Bolshevism, both because of Bogdanov's influence in the faction and because empiriocriticism's emphasis on activity suited the activism and voluntarism of Bolshevism. The association was an embarrassment to Lenin who distrusted empiriocriticism's eschewal of common-sense epistemology and its heady avant-gardism, manifested in Lunacharskii's attempt to supplement socialism with a secular religion celebrating humanity's powers of self-creation ('God-building'). In addition, the Mensheviks stressed that empiriocriticism was a Bolshevik philosophy in order to cast their opponents as revisionists and opportunists. In 1909, when Lenin no longer perceived an alliance with Bogdanov to be politically expedient, he broke a long-standing truce on philosophical

matters and attacked empiriocriticism as a heresy. Thereafter, dialectical materialism was deemed the theoretical foundation of Bolshevism.

In *Materializm i ėmpiriokrititsizm (Materialism and Empiriocriticism)* (1909), Lenin dismisses the idea that empiriocriticism transcends the dichotomy of materialism and idealism. On the contrary, it is a blatant form of idealism that represents matter as a construction of the mind. It therefore falls to the same arguments that defeated Berkeley and Hume. The new empiricism is motivated, Lenin argues, by the latest findings of physics, which suggest to the intellectually naïve that 'matter has disappeared' or that the laws of nature are human inventions. Such conclusions, Lenin maintains, are entirely wrongheaded. He defends a robust form of philosophical realism. The external world exists objectively prior to and independently of thinking subjects. We obtain knowledge through sense perception, on the basis of which we build theories of the world. Lenin wavers between direct and representative realism, suggesting sometimes that the mind is in immediate cognitive contact with reality and sometimes that perceptions and ideas are images or 'photographs' of objects. Either way, Lenin believes our conceptions may accurately represent reality. Objective truth is possible, though our theories are often only relatively, not absolutely, true. The criterion of truth is practice: a theory's truth explains why it is a reliable guide to practice.

Lenin denies that philosophy can dictate to science. Materialism establishes only that matter exists objectively, a view held by anyone who 'has not been an inmate of a lunatic asylum or a pupil of idealist philosophers'. Otherwise, it falls to science to establish what matter is like.

For the most part, Lenin's philosophy differs from Plekhanov's only on minor points (he rejects Plekhanov's view that sensations are 'signs' rather than depictions of objects) and in matters of emphasis (Lenin focuses on philosophy's relation to science rather than the philosophy of history). However, *Materialism and Empiriocriticism* reflects Lenin's Bolshevism in two respects. First, his obsession with objectivity fits his idea of the revolutionary vanguard armed with the truth that will lead the proletariat to victory. Second, his idea of the *partiinost'* ('partyness') of philosophy - the idea that philosophical positions are intrinsically related to class interests - politicizes all philosophical enquiry and suggests that philosophy is a weapon in the class war (see Partiinost').

The influence of *Materialism and Empiriocriticism* was enormous. Under Stalin, it was portrayed as a model of philosophical excellence and the foundation of a new, Leninist stage in Marxist thought (Lenin's debt to Plekhanov was forgotten). The concept of *partiinost'* was invoked to legitimize the criticism of philosophical theories on purely political grounds, and the coarse style of Lenin's writing, with its use of invective and abuse, became the official medium of philosophical discourse.

Materialism and Empiriocriticism was not Lenin's last word on philosophy. Between 1914 and 1916, he made a study of Hegel's philosophy. Lenin's notes, published 1929-30, show him arriving at a greater appreciation of the significance of dialectics. He declares that empiriocriticism was criticized more from the perspective of vulgar Feuerbachian materialism than Marxism, and suggests that the theorists of the 1910s (himself included) failed to understand Marx properly because of their ignorance of Hegel's *Science of Logic*. These and other aphorisms were later much quoted by Soviet philosophers endeavouring to elevate discussion beyond the crude materialism inspired by Lenin's early book.

3 Controversies in the 1920s

Although many areas of Soviet culture flourished after the Revolution, philosophy was beleaguered from the outset. First, the shortage of 'red specialists' meant that the 'philosophical leadership' charged with developing the Marxist ideas that had enabled and empowered the Revolution had to include non-Bolsheviks whom the Party viewed with suspicion. Moreover, when the first Soviet philosophy journal, *Pod znamenem marksizma (Under the Banner of Marxism)*, was launched in 1922, it was attacked on the grounds that the very idea of Marxist philosophy was confused. S.K. Minin argued that since philosophy had only ever served to foster ideological myths in the service of the oppressing classes, it should simply be displaced by science. 'Science to the bridge, philosophy overboard!' was Minin's slogan.

This 'liquidationism' was quickly (and unfairly) dismissed as a species of philistine anti-intellectualism. However,

the issue of philosophy's relation to science was soon the focus of a bitter controversy that divided the Soviet philosophical world: the debate between the 'mechanists' and the 'dialecticians' (or 'Deborinites').

The mechanists included scientists such as A.K. Timiriazev (1880-1955) and philosophers such as I.I. Skvortsov-Stepanov (1870-1928) and L.I. Aksel'rod (1868-1946). Bogdanov was associated with the movement, as was the Bolshevik luminary Nikolai Bukharin (1888-1938), whose *Teoriia istoricheskogo materializma (Historical Materialism)* had been published in 1921. Many mechanists were reductionists, who thought that science would eventually provide an exhaustive account of reality. But others, such as Aksel'rod, were drawn to mechanism by its defence of the autonomy of science. The mechanists argued that philosophy's role was to elucidate the concepts and laws employed by science, but not to interfere with scientific inquiry on a priori grounds.

The dialecticians included I.E. Sten (1899-1937), N.A. Karev (dates unknown), I.K. Luppol (1897-1943), V.F. Asmus (1894-1975) and the single most influential philosopher of the period, A.M. Deborin (1881-1963). Students of the history of philosophy, they saw their principal task as a materialist reworking of Hegelian dialectics. On this view, since the dialectical enterprise seeks to explain the very possibility of cognition, it cannot proceed by empirical generalization from scientific practice. Without philosophy, science cannot understand itself.

Between 1924 and 1929, the two schools fought in the literature and at gatherings in philosophical institutions. Despite the significance of the issues, neither side could move the other by argument and the debate degenerated into political wrangling. Eventually, the Deborinites used their greater institutional power to have their opponents condemned as revisionists.

The dialecticians' triumph was short-lived. In March 1930, a group of young activists at the Institute of Red Professors, led by M.B. Mitin (1901-87), accused their Deborinite teachers of 'formalism' and idealism. Since the mechanists had been (implausibly) portrayed as ideologists of Bukharin's 'right deviationism', Mitin (yet more implausibly) argued that the dialecticians were allied with the Trotskyite 'left deviation'. The young radicals called for a 'battle on two fronts in philosophy', urging that Soviet philosophy had to be 'Bolshevized'. Despite spirited resistance, Deborin and his followers were crushed. In June 1930, *Pravda* published an article by Mitin, Ral'tsevich and Iudin complete with editorial endorsement. Dubbed 'Menshevizing idealists' (Stalin's term), the Deborinites were forced from power.

Fortunately these controversies are not all that occurred in Russian Marxist philosophy in the 1920s and early 1930s. Two thinkers on the fringes of the subject made significant and enduring contributions. The first was the psychologist L.S. Vygotskii (1896-1934), who sought a way between mechanistic, reductionist models of the mind and introspectionist accounts that put the mental beyond systematic analysis. Inspired by Marx, Vygotskii argued that the dominant 'reflexological', stimulus-response models were too unidirectional to account for the human mind. The 'higher mental functions' are *mediated* forms of psychological activity; human beings actively change their environment to create new stimuli that serve to control their behaviour. We fashion artefacts - tools and signs - for manipulating both the world and the behaviour the world calls from us. Vygotskii originally introduced the concept of mediation to supplement the stimulus-response model. However, he became fascinated with the concept of meaning, arguing that semiotic mediation creates not a new class of stimuli, but a completely transformed psychological relation to reality. Vygotskii argued that since the 'mediational means' are cultural creations, preserved in the interpretative practices of the community, mind itself is a cultural artefact. The child's mind develops not through merely natural evolution, but by the 'internalization' of social practices. Vygotskii's writings were blacklisted shortly after his death in 1934, but his legacy was preserved by his followers - including A.R. Luria (1902-77) and A.N. Leont'ev (1904-79) - in the 'cultural-historical' school of psychology.

Similar themes emerge in writings attributed to V.N. Voloshinov (*c*.1895-1936) (which may have been written by M.M. Bakhtin (1895-1975)). In *Marksizm i filosofiia iazyka (Marxism and the Philosophy of Language)* (1929), Voloshinov argues that the problematic relation between base and superstructure can be illuminated by a Marxist theory of language. This is because superstructural phenomena are ideological in kind and ideology is a system of signs. Voloshinov rejects both psychologistic and abstract structuralist views of language, stressing that the linguistic sign exists in verbal utterance: meaning is inherently tied to use. This introduces a social dimension, since language is inherently dialogical. All utterance is explicitly or implicitly directed to another (or to oneself-as-another). This view has psychological consequences, for consciousness exists only in its material

embodiment of signs, and signs exist only in dialogue in a socio-cultural setting. The mind is semiotically constructed in social space, and the structure of thought (inner speech) issues from the internalization of the forms of outer utterance. Voloshinov writes: ‘Individual consciousness is not the architect of the ideological superstructure, but only a tenant lodging in the social edifice of ideological signs’.

Though suppressed in the USSR, Voloshinov’s writings influenced Roman Jakobson and the Prague Linguistic Circle, and, like Vygotskii, his ideas have attracted a significant following in the West (see Bakhtin, M.M. §§1-2).

4 The depths of the Stalin era

In the 1930s, all spheres of Soviet culture were brought to heel and made to glorify the Soviet Communist Party and the deeds of its General Secretary. The philosophers of the ‘new philosophical leadership’ eulogized Lenin’s genius (how fortunate that Stalin was ‘Lenin today’!) and spun a bizarre mythology about class enemies in philosophy, especially the Menshevizing idealists, now ‘discovered’ to be ‘fascists’ and ‘terrorists’.

In 1938, the tenets of Marxism-Leninism were codified in the *Istoriia kommunisticheskoi partii sovetskogo soiuza (Bol’sheviki). Kratkii kurs (History of the Communist Party of the Soviet Union (Bolsheviks). Short Course)*. The infamous fourth chapter, supposedly written by Stalin himself, presents the principles of dialectical materialism in schematic, canonical form, and offers strikingly simplistic examples of its application in historical materialism: that the base determines the superstructure follows from the primacy of the material over the ideal; class struggle reflects the dialectical law of ‘the unity and struggle of opposites’; revolutions are instances of the transformation of the quantitative into the qualitative, and so on. (The law of the ‘negation of the negation’ was omitted, no doubt because it implies the mutability of all things, including Soviet communism.) Both the sense of history, and the thirst for argument, evident respectively in Plekhanov’s and Lenin’s writings, are conspicuously absent. In this primitive form, Marxist philosophy was propagated throughout the Soviet Union. Every literate person was compelled to assimilate the ‘fourth chapter’, and professional philosophers expounded it *ad infinitum*, unable to transcend its horizons for fear of challenging Stalin’s authority.

Just as the Party put science in the service of industry, so the humanities were devoted to ‘the engineering of the human soul’, as Stalin described the role of Soviet literature. Philosophy was placed under the aegis of the Central Committee’s Department of Propaganda and Agitation, directed between 1939 and 1947 by the philosopher G.F. Aleksandrov (1908-61). In this climate, many genuine philosophers turned to the history of philosophy, where they could still study the European tradition. However, before long this area was also the focus of political controversy. In the war years, when ideological constraints were otherwise somewhat relaxed, Soviet works which gave a sympathetic rendition of German classical philosophy were denounced. For this reason, in 1944 the third volume of a collective *History of Philosophy*, which included Aleksandrov himself among its editors, was targeted by the Central Committee, even though its authors had previously received the Stalin Prize.

The post-war years saw a remarkable clampdown throughout Soviet culture. This campaign, led by A.A. Zhdanov, combined fierce allegiance to Marxist-Leninist principles with a virulent form of Russian nationalism. The chauvinistic climate is well illustrated by another controversy surrounding Aleksandrov. In 1947, his textbook *Istoriia zapadnoevropeiskoi filosofii (A History of Western European Philosophy)* (1946) (which is entirely orthodox in spirit) was vilified as ‘abstract’, ‘bookish’, ‘formal’ and ‘lacking *partiinost’*’ largely for its failure to emphasize the supremacy of Russian over Western philosophy. The philosophers who opposed this trend were eventually accused of ‘cosmopolitanism’, ‘sycophancy before bourgeois philosophy’ and ‘kowtowing to the West’.

The Party also used philosophy to interfere in the natural sciences. In the late 1940s, theories in chemistry, cosmology and physics, especially relativity theory and quantum mechanics, were all criticized on ideological grounds when apparently in tension with dialectical materialism. And in the early 1950s, cybernetics was dismissed as a pseudo-science, since its global explanatory pretensions were at odds with Marxism. Chauvinism about Russian scientific achievements reached ridiculous heights, and the myth of a ‘proletarian science’ took hold. The most conspicuous example was the Party’s long-standing support for T.D. Lysenko’s Michurinist genetics, which defended the inheritance of acquired characteristics (suggesting that the qualities of New Soviet Man could be genetically inherited by subsequent generations). These tragicomic episodes did incalculable damage to Soviet science.

5 Renaissance after Stalin

That any kind of philosophical culture survived the Stalin period is a remarkable fact. A significant number of philosophers perished in the purges, but a handful of participants in the debates of the 1920s survived and continued to teach. Although unable to publish much in this period, philosophers like Asmus, O.V. Trakhtenberg (1889-1959), P.S. Popov (1892-1964) and M.A. Dynnik (1896-1971) gave significant courses at Moscow University. B.M. Kedrov (1903-85) was also influential, despite being then estranged from the University for political reasons. In addition, several prominent psychologists, such as Luria, Leont'ev and S.L. Rubinshtein (1889-1960), who were members of the philosophy faculty at Moscow University, made a vital contribution to keeping philosophy alive. These older thinkers found a new generation of philosophers among students resuming their education after the Great Patriotic War. This generation, which includes E.V. Il'enkov (1924-79) and A.A. Zinov'ev (1922-) (who later emigrated, writing the dissident novels, *The Yawning Heights* and *The Radiant Future*), is sometimes called the 'iflitsy', after the unusually vibrant Moscow Institute of History, Philosophy and Literature (IFLI), where many of them had studied before the war. Despite the stifling atmosphere in most academic institutions, and the shortage of materials, the new generation was determined to renew Soviet philosophy by going 'back to Marx'. In the 1950s, their work focused on two principal areas. First, they explored the dialectical method, sketched by Marx in his 'Introduction to a Critique of Political Economy' and deployed in *Capital*. This produced scholarly readings of Marx's texts in which the 'method of ascent from the abstract to the concrete' was developed into a full-blown account of concept acquisition and theory construction, to be contrasted with empiricist views of scientific knowledge. Most significant is Il'enkov's *Dialektika abstraktnogo i konkretnogo v 'Kapitale' Marksa (The Dialectics of the Abstract and the Concrete in Marx's 'Capital')* (1960), but the writings of Zinov'ev, B.A. Grushin (1929-) and G.P. Shchedrovitskii (1929-93) (who formed the Moscow methodological circle) were also influential.

These methodological writings explore the preconditions of scientific understanding, not in abstract Kantian terms, but historically. This project naturally raised the question of the nature and origin of mind itself. How can a material world come to contain beings able to engage in the project of understanding themselves and their world? The question was answered by developing a philosophical anthropology centred on the concept of *activity*. In the 1960s, the Georgian philosopher Merab Mamardashvili (1930-90), who worked in Moscow, produced an influential study of the concept of consciousness in Marx's thought, developing the concept of 'transmuted forms'. And Il'enkov developed his controversial account of 'the ideal', according to which humanity's active engagement with nature results in the objectification of non-material properties and relations in the natural world. We enculturate our material environment, and become conscious beings in so far as we appropriate social activities constitutive of humanity's spiritual culture. In this way, Il'enkov develops the Vygotskian idea that culture is a precondition of the existence of individual consciousness.

The work of this new generation, mostly published in the Khrushchev 'thaw', stimulated lively debate in many philosophical institutions, especially Moscow's Institute of Philosophy. At this time, a translation of Marx's *Paris Manuscripts* (prepared by Il'enkov among others) became available, provoking further interest in a critical, anthropocentric Marxist philosophy. However, many of the Stalinist old guard maintained their positions in the academy, and the Party continued to exercise control over philosophical discussion. Huge editions of one-dimensional Marxist-Leninist textbooks, such as the *Fundamentals of Marxist-Leninist Philosophy*, were used to disseminate the worldview of the Communist Party in all institutions of higher education. Contact with Western philosophers and their works was limited. Moreover, by the mid-1960s, the thaw began to ice over and the mood of creativity and optimism faded.

Although the next two decades lacked the inspiration of the early 1960s, there were many prominent controversies, often conducted on the pages of *Voprosy filosofii (Questions of Philosophy)*, which had been the principal Russian philosophy journal since 1947. Some, such as the discussions of reflection theory and the laws of dialectics, were merely variations on themes of Marxist orthodoxy. Others, like the ongoing debates about the nature of Marxist philosophy and the relation between dialectical and formal logic, were more serious. There was a revival of interest in ethics, which had previously been ruled out by the orthodox view that morality was destined to 'wither away' under communism. Influential figures were O.G. Drobnitskii (1933-73), tragically killed in an air disaster, and Iu.N. Davydov (1929-). Knowledge of contemporary Western philosophy became more widespread, due to the

efforts of such thinkers as A.S. Bogomolov (1927-93) and A.F. Zotov (1931-), though works developing Soviet Marxism in critical dialogue with Western philosophy were few; the most successful was *Sub' 'ekt, ob' 'ekt, poznanie (Subject, Object, Cognition)* (1980) by V.A. Lektorskii (1932-), which ably contrasts an activity-centred epistemology with a variety of Western views.

One significant debate conducted in both academic and popular journals concerned the extent to which human psychological capacities are genetically determined. Many Soviet philosophers and psychologists, such as Il'enkov, Leont'ev, V.V. Davydov (1930-) and F.T. Mikhailov (1930-) argued that Marxism is committed to a conception of individuals as socially constituted beings, whose principal mode of psychological inheritance is cultural rather than biological. In contrast, their nativist opponents, who included scientists as well as such philosophers as D.I. Dubrovskii (1929-), argued that this view contradicted the physical basis of the mental. Though the theoretical value of these polemical exchanges is limited, the political dimensions of the debate are interesting. The nativists resented philosophical interference in what they took to be an empirical matter. In addition, they took their opponents' contructivism to be motivated by dreams of the creation of a 'New Soviet Man', and they turned to genetics to define a sphere where the individual was immune to social influence. The constructivists in turn saw nativism as reactionary, the result of a dehumanizing scientism, inspired by fascination with the so-called 'scientific-technological revolution'. Human beings are not just self-organizing machines to be manipulated by the state, however much they were made so by Stalinism, but beings infinitely capable of self-transcendence and renewal if society can only create the appropriate conditions.

6 *Perestroika* and dissolution

Soon after coming to power in 1985, Gorbachev instigated reforms designed to restructure the Soviet socioeconomic order (*perestroika*) and to encourage more critical debate and public accountability (*glasnost'*). To this end, he disavowed the Party's claim to privileged access to objective knowledge and, calling for greater democracy, urged an end to the 'bureaucratization' of Soviet life. Soviet philosophy underwent significant liberalization. Instruction in Marxism-Leninism became no longer mandatory in Soviet institutions of higher education; indeed, the term 'Marxism-Leninism' was soon abandoned. *Voprosy filosofii* published debates about democracy, the rule of law and civil society, discussions of the history of Soviet philosophy (never previously a possible subject of debate), articles by Western thinkers, and hitherto banned works by Russian philosophers, such as Berdiaev and V.S. Solov'ëv (1853-1900).

The ethos of 'official' Soviet philosophy under *perestroika* is illustrated by the writings of I.T. Frolov (1929-), then advisor to Gorbachev and editor-in-chief of *Pravda*. In his book *Man, Science, Humanism* (1986), Frolov speaks out against Soviet Prometheanism, arguing that although we look to science to improve the conditions of human life, we must recognize that scientific progress has brought dramatic threats to the future of humanity. A critical and humanistic Marxism strives to put science 'in the service of humanity'. Frolov stresses the 'open character' of Marxist theory, urging that its tenets are not absolute truths. He attacks the follies of proletarian science, suggests compromise solutions to entrenched Soviet controversies (for instance over the genetic basis of the mental), and urges dialogue with Western thinkers.

Though more liberal than previous party lines, Frolov's position retains the idea that all issues are best addressed from the perspective of an all-encompassing theory of humanity's place in nature, a theory whose fundamental tenets are beyond dispute. Frolov's writings represent a broadening of Soviet orthodoxy, but the spirit of radical criticism remains absent.

The theme of humanism was central to much philosophical discussion under *perestroika*. The concept of a person (*lichnost'*) as a centre of moral agency came to the centre of discussion, complementing debates about ethical responsibility and legal consciousness. This person-centred approach was reflected in a new official textbook, *Vvedenie v filosofiiu (Introduction to Philosophy)* (1990), focused on problems of human existence instead of the primacy of materialism and the laws of the dialectic. There was a renewed interest in the anthropocentric Marxism that flourished in the Khrushchev thaw, especially Il'enkov's philosophy, which, it was argued, anticipated many themes openly discussed under *glasnost'*.

The new climate precipitated a number of heartfelt public discussions on the question 'Is Marxism dead?' A number of significant philosophers, such as E.Iu. Solov'ëv (1934-), K.M. Kantor (1922-), V.M. Mezhuev (1934-)

and V.I. Tolstykh (1929-) argued that Marx should not be quickly blamed for the failed Soviet experiment; Marxist thought deserves continued study like any other major philosophical system. In contrast, others, like A.S. Tsipko (1941-), poured scorn on the pretensions of Marxist philosophy, stressing the emptiness of Marx's views and their inapplicability to contemporary reality. These discussions reveal an intellectual world in crisis, disoriented by the diminution of its central authorities.

With the collapse of the Soviet Union in 1991, Russia's commitment to Marxism was abandoned entirely. Although Marxist influences are often evident in their work, few Russian philosophers now see themselves as contributing to the Marxist tradition. The thirst for a grand explanatory perspective is no less intense, but Russian thinkers now seek one elsewhere, in the Russian religious philosophy suppressed by the Bolsheviks, or in Western ideas, such as Foucauldian postmodernism (taken up by V.A. Podoroga (1946-) and his associates). Where these developments will lead is an open question. It seems, however, that the history of Russian Marxism is over.

Marxist thought in Latin America

Marxism is a theory offering a critique of capitalist political economy. Marxism also views itself as an instrument or means of changing the world from a capitalist to a socialist (and/or communist), economic and political order. Given its interest in economic and political change, Marxism involves a philosophy of history which depicts the possibility of and conditions for change from a capitalist to a socialist order. Marxist intellectuals perform the dual task of analysing the failures or limitations of capitalist economic and political structures. The theory also proposes and evaluates socialist alternatives.

Latin American Marxism developed out of its own historical, economic, political and cultural conditions. Influenced by Lenin's analysis of imperialism as the highest stage of capitalism, it directed the critique of capitalist political economy towards the capitalist world market and its disadvantageous effects for the countries, particularly the impoverished classes and social sectors, of the Latin American and Caribbean regions. Latin American Marxism-Leninism argues, on political and economic grounds, that national liberation cannot be achieved without liberation from imperialism.

Marxists believe that although the protagonists of history's political projects are the workers (or if Leninist, the workers together with the peasants), in the end the interests of these groups represent the universal interests of humankind. Marxist political discourse often uses broader categories than those of 'workers' or 'peasants' to designate the agents of political emancipation, employing terms such as 'the people', 'the popular sectors' or 'the revolutionary masses'. In this way Marxism attempts to broaden its political base so as to make its goals more effective. The political discourse of the Cuban Revolution of 1959 and the Nicaraguan Sandinista Revolution of 1979 exemplify this practice.

There are and have been many differences among Marxists because of the different approaches to criticizing capitalism as well as the different conceptions held by those who profess a commitment to the ultimate Marxist goal of creating a nonexploitative socialist society. Representative issues in Latin American Marxism may be illustrated by focusing on three questions: the problem of orthodoxy, the socialist construction of a national identity and socialism's relation to ethics, religion and culture. In addressing these issues, this entry draws significantly from the work of Peruvian Marxist José Carlos Mariátegui, a prominent founder of Latin American Marxism.

1 The problem of orthodoxy

The mechanisms for implementing Marxist orthodoxy were not clear when the ideology was first introduced and then began to take shape between the 1870s and 1920s. The newness of socialist and communist ideas led Marxists to view themselves as future-oriented and revolutionary thinkers. Among the best-known early Latin American Marxists were the Argentine Aníbal Ponce, the Peruvian José Carlos Mariátegui and the Cuban Julio Antonio Mella. Mella was a university student leader strongly influenced by the thought of the Cuban patriot José Martí. Ponce was involved in education and publishing, wrote on socialist humanism and from 1923-5 coedited, with the Argentine positivist philosopher José Ingenieros, the *Revista de Filosofía, cultura, ciencias, educación (Journal of Philosophy, Culture, Science, Education)* (1915-29). Ponce became sole editor after Ingenieros's death in 1925.

Mariátegui, a journalist and social critic, was acknowledged as the most influential of the early Latin American Marxist thinkers. Author of *Seven Interpretive Essays on Peruvian Reality* (1928) and editor of the journal *Amauta: Revista mensuel de doctrina, literatura, arte, polémica (Amauta: Monthly Review of Doctrine, Literature, Art and Polemics)* (1926-30), he developed a highly original position in Latin American Marxism by stressing the importance of ethnicity, or indigenous culture, in the construction of national identity. He did so by maintaining a flexible position with regard to the relationship of Marxism to the latest theoretical currents from Europe and the USA, namely Bergsonian philosophy, pragmatism and psychoanalysis (see Bergson, H.-L.; Pragmatism). He also rejected the notion of an essential antagonism between Marxism and religious thought, thereby breaking with the orthodox Marxist view that a materialist philosophy of history necessarily presupposes a materialist metaphysics. Mariátegui expounded his original ideas as part of his commitment to both a Leninist Marxism and the project of building a socialist society in Peru. As founder of the Socialist Party of Peru, he was criticized during his short life for some of his views by the Communist International. The 'errors' in his ideas were especially criticized during

the Stalinist era, until a resurgence of interest in his work took place in the 1960s and 1970s.

For the first generation of Marxists, orthodoxy was less of a problem than for succeeding generations, since their task was to forge the new political philosophy which was not without codification. Marxism's link between theory and practice inevitably has raised the problem of orthodoxy and heterodoxy. Marxism's role is explanatory and predictive as well as conceptual. It is a theory whose goal is to create a determinate set of political effects. Its difficult aim is to construct a society without class exploitation.

Of fundamental historical importance to Marxism have been the questions of the scientific correctness of the theory designed to change the world and the correct political orientation of the leaders charged with developing and applying the theory in historical conditions, subsequent to those experienced by Marx and Engels. Depending on one's critical approach, Marxist theory can range from a nonpolitical intellectual analysis and critique of various aspects of capitalism as they affect human life and society to a dogmatic exposition and defence of the main theses accepted collectively at Communist Party congresses.

Orthodoxy is a relative concept. A position is orthodox in relation to the dogmas, truths, or methods that are taken to be central to a particular doctrine or school of thought. A Marxist thinker may be a dissident with respect to one school of Marxism while representing an orthodox position in another. The degree to which a Marxist position is free from orthodoxy is determined by the extent of its ability to question the closest Marxist authority with which it is associated. Marxist politics tend to impose a collective discipline over an individual's analysis of social reality. In cases where Marxist philosophy is practised within a socialist state that permits only one political party, the collective constraints over individual thought can be highly exacting. Although not all Marxists defend a one-party political system, those who do assert that the defence of the emerging socialist state against imperialism must take the highest priority.

Traditionally, Marxism relies on the methodologies of dialectical and historical materialism. From Hegel's self-validating account of dialectical thinking, Marxists inherited the view that dialectics provide an insuperable scientific conception of reality (see Hegel, G.W.F.). Using the logic of dialectical materialism, orthodox Marxism holds that reality is material and that it changes by oppositional as well as by qualitative movements governed by dialectical laws known to the human mind. Marxist orthodoxy gave the name of 'scientific socialism' to this perspective. Applying a dialectical and material concept of change to history, historical materialism posits that the development of history is caused by material (primarily economic) factors, that history progresses through stages and that the change from one historical stage to another takes place when internal contradictions lead the old economic structures to be phased out in favour of newer, stronger and more universal elements. Historical materialism postulates that at the point of qualitative change between capitalism and socialism there lies a social revolution that will dismantle the old class divisions within society and lead eventually to a classless society in which the exploitation of human beings by human beings ceases to exist.

As a political philosophy Marxism argued that such exploitation can only be overcome by a social and political revolution in which the working class plays the dominant and leading liberatory role. After Lenin, Marxism-Leninism broadened the class of revolutionary political subjects to include both workers and peasants, students and intellectuals, all of whom had the same revolutionary aspirations. The Italian Marxist Antonio Gramsci (1891-1937) called the revolutionary intellectuals who supported the social revolution 'organic intellectuals'. In Latin America this view influenced many leftist intellectuals to back popular revolutionary movements led by Marxist leaders, as in Cuba and Nicaragua. The Marxist-Leninist-Gramscian influence, augmented in the 1960s by the political impact of leaders such as Ernesto 'Ché' Guevara, distinguished a wide sector of Latin American Marxism from Western European critical Marxism, whose intellectual roots were closer to Hegel, Marx, phenomenology, existentialism and critical theory (see Critical theory; Existentialism; Phenomenology in Latin America). In Western Marxism, the materialist view of the worker and peasant protagonists of history is downplayed while issues such as alienation, the individual and social justice and the combined effects of oppressive class, race, and gender relations in the critique of capitalist economics are foregrounded.

Despite the problem of orthodoxy which delimits the production of Marxist philosophy and social thought, as a critique of capitalism and capitalist social structures Marxism yields some important and original insights which are absent from bourgeois philosophy and ideology. Mariátegui's focus on the construction of an Indohispanic

socialism in Peru is a case in point.

2 The construction of a national identity

In keeping with the theory of historical materialism, Mariátegui (1928) held that societies evolve according to the laws of their socioeconomic development and that historical progress involves the surpassing of feudalism by capitalism and of capitalism by socialism. Apart from this traditional framework of historical materialism, Mariátegui introduced a number of variants into his concept of socialism which, when considered together, lay the foundations for a specifically Latin American approach to socialist theory. Mariátegui questioned the linear concept of history as it applied to the narrative of the superiority of European culture over the indigenous cultures of the Americas. He took the Spanish conquest of the Inca civilization to represent the defeat of a highly competent form of social organization by a less competent one. He claimed the conquest symbolized a rupture within the economic organization which grew out of the experiences of the earliest Peruvian people. These people combined a simple life with a highly sophisticated economic system which was based on hard work, discipline and the satisfaction of the people's material needs. By referring to the pre-Columbian Inca empire as a central, although defeated, player in the history of Peru, Mariátegui demonstrated that Peru's national identity should not be conceived without giving a prominent place to its indigenous people. As a Marxist his goal was to contribute to the formation of an Indohispanic socialism in Peru. This position involved, on the one hand, convincing non-Marxists that socialism was a superior system to capitalism in Peru, while on the other hand, convincing the white and mestizo minorities (including socialists) that the disenfranchised indigenous population of Peru was an essential and irreplaceable part of its national identity and character.

As a member of a generation of Latin Americans critical of positivist philosophy, Mariátegui combined a political interest in Marxism with other artistic and intellectual interests (see Anti-positivist thought in Latin America; Positivist thought in Latin America). He promoted the Peruvian pro-indigenous literary movement of *indigenismo* (indigenism) and the new thinking of the European avant-garde. He supported the merit of thinkers like Friedrich Nietzsche, Sigmund Freud, James Joyce and Miguel de Unamuno and linked aspects of their views and teachings to his socialist interpretation of human and social reality. Mariátegui's appreciation of the value of myth led him to the insight that the relationship between the Indian and the land could not be understood simply in materialist or strictly modern secular terms. It must include a full account of the Indian's deeply-rooted spiritual belief that life springs from the land and returns to the land. He perceived the indigenous peasants as socially oppressed both as a class and in terms of their racial and ethnic status. He argued for a notion of national identity that would allow the Indians to come to prominence. Mariátegui's analysis called for Marxist theory to be reformulated so that it would take into account both class and ethnicity, including the cultural aspects of ethnic beliefs.

3 Ethics, religion and culture

The concept of human nature articulated by Mariátegui included a blend of existential, pragmatist, and Marxist influences (see Existentialism; Pragmatism). It was best characterized by a rejection of Cartesian rationalism and positivism (see Rationalism). He followed the Italian idealist philosopher Benedetto Croce in holding that, without a set of moral principles, specifically a principle condemning human exploitation, Marx's critique of capitalist economy would not make sense (albeit that Marx was not interested in developing a moral philosophy). Influenced by the French labour theorist Georges Sorel, Mariátegui argued that socialism had an ethical function, which was to create a 'morality of producers' in the process of struggling against capitalism. Therefore, Mariátegui was interested in articulating a work ethic based on socialist principles which would raise the moral consciousness of workers as they aimed to transform the exploitative conditions of class society.

Mariátegui departed from a 'scientific' dialectical materialist account of social change by representing the proletariat, or working class, as an affirmative rather than a negative, social and political force. In his early writings Mariátegui argued that the characteristic gesture of the bourgeoisie was to negate, while that of the working class was to affirm. He counterposed bourgeois nihilism and decadence with working class optimism and confidence. In the Hegelian version of the dialectic, negation (rather than affirmation) was the process which moved history forward. This led Marxism to emphasize revolution as the negation of a previously established political order. However, in his account of Peruvian history, Mariátegui argued for socialism on positive grounds. Peruvian capitalism was described as weak and unable to undo the power of the rural conservative sectors, which retarded economic development. Socialism was depicted as the one solution that would incorporate the benefits of

capitalism (creativity, discipline, productiveness) while accommodating the communitarian interests of the indigenous population.

In the light of Mariátegui's portrayal of the workers and indigenous peasants as positive social forces, it could be argued that his concept of ethics, with its connection to socialism, was as close to Nietzsche's idea of a superior morality as to Marx's concept of social revolution. Mariátegui saw the advent of socialism as resulting from its own vigorous and undisputed success, not as a result of a class war. The work ethic he advocated contained a forceful and explicit rejection of what Nietzsche called a 'slave morality', a moral system which was reactive rather than self-initiated in its positing of moral principles and/or practices (see Nietzsche, F. §8). Mariátegui also rejected the notion of a teleological end-state after the achievement of which history would end and all oppression would cease. He declared that no revolution can foretell a subsequent revolution, despite the fact that seeds of political change may have been planted. Like William James, Mariátegui attributed to human beings a basic 'will to believe'. However, he also held, after Sorel, that the object of the will to believe need not be a religion as traditionally understood: it could be a belief in social revolution. Such a belief, like religion, would satisfy the human hope for a better world. Mariátegui therefore subscribed to an open-ended concept of revolution, which favoured an adaptation of Marxist ideas to new historical circumstances, including new trends in theory beyond those with which Marx was acquainted, such as Hegelian philosophy.

Mariátegui's views have been of interest to religious leftists, particularly Christians, motivated by a belief in a just and nonexploitative society, such as those committed to a theology of liberation (see Liberation theology). In the *Seven Interpretive Essays on Peruvian Reality* (1928) he claims that it is a fundamental error for Marxists to attack the clergy and the church as if these were the principal obstacles to socialist change when the real enemy is the socioeconomic structure of society. He argued that the will to believe is a basic factor of human existence and that historical materialism as a theory of historical development should not be confused with philosophical materialism as a comprehensive theory of all reality. This view, conjoined with the view that, according to myth Indians regard the land as their common mother, contributed to Mariátegui's most important theses that the exploitation of the Indians was due to the land tenure system of Peruvian society and that their liberation could only take place through a socialist structure respectful of the Indians' ancient relationship to the land and the inherited collective practices of working it. His position suggested that the acceptance of modern Western standards of development should be tempered by respect for the forms of communal organization and bonding which characterize the lives of Peruvians whose cultural legacy is of pre-Columbian (non-Western) indigenous origin.

Mariátegui united his defence of an Indohispanic Peruvian socialism with a strong Marxist anti-imperialist statement. He argued that as long as imperialism exists, a Latin American society cannot be nationalist unless it is socialist. The economic and political structure of imperialism prevents the full realization of nationality in countries whose economic development is locked into a weak and backward capitalist structure controlled by foreign economic interests. He noted that imperialism implies racism in that the cultural values imposed by an imperialist north-over-south continental order were the values of a white bourgeois class, imported into the south by the white privileged classes of Latin America. The latter, he claimed, failed to question their own involvement in an exploitative and racist system. Mariátegui challenged capitalism in terms that emphasized class, race and a nation's dependent status on the world market without promoting divisiveness or separatism.

Although Latin America has produced some well-known Marxist academic philosophers, including the Heideggerian Marxist Carlos Astrada (1894-1970) and the Marxist aesthetician Adolfo Sánchez Vázquez (1915-), it is José Carlos Mariátegui, a self-educated working class mestizo intellectual, to whom most contemporary scholars turn when the subject of inquiry involves the articulation of a specifically regional, that is Latin American, Marxism.

Masaryk, Tomáš Garrigue (1850-1937)

Masaryk was a philosopher, sociologist, politician and first president of the Czechoslovak Republic (1918-35). Initially he aimed to change the Habsburg monarchy into a democratic federal state, but during the First World War he began to favour the abolition of the monarchy and, with the help of the Allied powers and the Czechoslovakian foreign armed forces, won independence for his nation. Masaryk's philosophy of history posited democracy achieving victory over theocracy as a stage in world evolution. He regarded democracy as both a political system and a humanistic world outlook.

Tomáš Garrigue Masaryk was born into a poor family and gained access to higher education only with difficulty. After grammar school in Brno and Vienna he studied philosophy and classical philology at the University of Vienna where he became a student of Franz Brentano. Having achieved his Ph.D. in 1876, he studied in Leipzig where he met Fechner and Wundt and befriended the young Husserl. Masaryk's 1879 habilitation thesis at the University of Vienna was *Der Selbtstmord als sociale Massenerscheinung der modernen Civilisation (Suicide and the meaning of civilization)*, which contained many ideas later developed and expanded in his philosophy. It concluded that suicide is a result of the prevalence of subjectivism, individualism and one-sided rationalism which had dismantled the Christian worldview. Masaryk sought the solution in an organic cultural synthesis, in education involving the unity of philosophy and science, theory and practice, in a new non-mythical religion, and in the reform of society according to sociological knowledge.

In 1882 Masaryk was appointed professor at the University of Prague. Here his focus went beyond academic activity, bringing supranational criteria to bear on provincial conditions and narrow national interests. Czech cultural life, until then looking exclusively to Germany, was becoming enriched with French and Anglo-American ideas, reflected in Masaryk's first philosophical work, *Základové konkrétné logiky (Fundamentals of concrete logic)* (1885). Although his most theoretical, this was a distinctly practical work, reflecting Masaryk's conviction that theoretical knowledge must serve life and his aim to reform society. Following Comte he created a system from which it is possible to deduce a consistent philosophical and simultaneously scientific worldview, but he placed a greater stress on psychology and ethics and their social role (see Comte, A.). He regarded metaphysics and theism as compatible with scientific knowledge.

Masaryk considered Czech politics of the time to be ineffectual, lacking both a theoretical basis and an ethical dimension. In *Česká otázka (The Czech question)* (1895) and other studies, he sought the *raison d'être* of the Czech nation and formulated a philosophy of Czech history. Its long humanitarian tradition based on religion he dated from the time of the Czech Reformation, continuing during the Czech National Revival at the beginning of the nineteenth century. This tradition, characterized by love of truth and genuine Christian life, was also democratic. Such humanitarian ideas parallel those of other progressive nations: consequently the Czech question represented the world question, and Masaryk believed its politics should be in harmony with this philosophy of history. His immediate target was the transformation of the Austrian multinational monarchy into a democratic federation, securing free evolution for all nations, and he actively pursued this idea until the outbreak of the First World War.

Masaryk's humanism centred around his interest in social problems, and he sympathized with many of the demands of the labour movement. He also concentrated on theory, balancing the philosophical and sociological perspectives of Marxism in *Otázka sociální (The social question)* (1898). He admired Marx's analysis of the importance of human labour, but rejected revolution as a solution to social conflict; rather, he emphasized reform in the spirit of humanism. His outlook is expressed by the aphorism ' Always for the worker, very often with socialism, rarely with Marxism' (Čapek 1938: 214).

Masaryk's interest in Russia culminated in his most extensive work *Rußland und Europa. Studien über die geistigen Strömungen in Rußland (The Spirit of Russia)* (1913). He analysed and critically evaluated the different trends in Russian thinking reflected in theoretical essays and literature. Dostoevskii's works, which he regarded as representing a new direction, challenge Masaryk's own conception of humanitarian philosophy.

The First World War proved a political turning point for Masaryk. He came to the conclusion that the Austrian

monarchy could not be reformed by inner forces, as it directly represented a metaphysical evil which was partially to blame for the outbreak of war. For that reason Masaryk opted for an independent Czech-Slovak state. Elected first president of the Czechoslovak Republic in 1918, he retired from academic life but did not cease to be interested in philosophy. He considered the Czech struggle to be part of a world revolution, a battle against theocracy which democracy can be expected to win, a viewpoint reflected in *Světová revoluce (The Making of a State)* (1924).

Masham, Damaris (1658-1708)

Damaris Cudworth, who became Lady Masham on her marriage to Sir Francis Masham in 1685, was an English moral philosopher who published two short treatises on moral philosophy. These show that she became a disciple of John Locke, although her philosophical background was in Cambridge Platonism. She applied Lockean arguments to defend the education of women; her anti-idealism led her to oppose Malebranche and his English followers, John Norris and Mary Astell; and she also corresponded with Leibniz.

Lady Masham was one of the very first English women to publish philosophical writings. The daughter of Cambridge Platonist Ralph Cudworth, she was also a very close friend of John Locke, who spent his last years at her residence in Essex. Unlike most women of her time, Damaris Cudworth was able to develop her interest in philosophy thanks to the fortuitous circumstances first, of being born into an intellectual family and, second, of becoming the close acquaintance of the leading English philosopher of his generation. Little is known of her education beyond the fact that she learned French but not Latin, which suggests that she had no more than the grooming deemed fit for a lady. In 1685, shortly after Locke's departure for exile, she married Sir Francis Masham, an Essex squire with a family of nine children. She herself had one child.

There are three sources for documenting Lady Masham's activities as a philosopher: her correspondence with Locke, her two short books, and her letters to Leibniz. Her two books were published anonymously and her biography of Locke was printed in abridged form in Moreri's *Grand Dictionnaire Historique* (1728). It is clear from Lady Masham's early correspondence with Locke (dating from 1682) that her introduction to philosophy was through the writings of the Cambridge Platonists, Ralph Cudworth, Henry More and John Smith (see Cambridge Platonism). However, the letters also show that she was receptive to Locke's views, and her two books (published with the encouragement of Locke) show her assimilation of his philosophy. In these she draws on Locke in her opposition to the Malebranchian idealism of Mary Astell and John Norris, and in her arguments for the education of women. The same anti-idealist position informs her critique of Leibniz. But her allegiance to Locke did not entail a repudiation of Cambridge Platonism in all respects: the Leibniz correspondence also includes a defence of her father against Pierre Bayle's imputation of covert atheism (see Bayle, P.).

The connecting thread of Lady Masham's thought is religious and moral. Her published writings are broadly Lockean in epistemology. *A Discourse Concerning the Love of God* (1696) is a critique of the correspondence between John Norris and Mary Astell which had been published as *Letters Concerning the Love of God* (1695). Lady Masham objected that Norris' occasionalist account of human love of God denigrates created things and undermines the bonds of society. By contrast, Lady Masham argued, humans come to know and to love God by observing the created world and comparing ideas 'received from *Sense* and *Reflection*'. She emphasizes practical morality, arguing that it is integral to religion. This position is developed in *Occasional Thoughts in Reference to a Vertuous or Christian Life* (1705) which contains an assessment of the role of reason in religious matters and, in particular, the relationship between religion and morality. Here she insists that civil and religious liberties are necessary for the exercise of virtue and that education is the key means to inculcate virtue. She displays an optimistic view of humankind as rational and social beings for whom the love of happiness is 'the earliest and strongest principle', happiness being the enjoyment of pleasure, and the pursuit of pleasure involving the regulatory exercise of reason which directs us to the greatest happiness. She is critical of Malebranche's pessimistic view of children as natural born sinners as a consequence of each child loving the body of its mother while in the womb. *Occasional Thoughts* concludes by arguing for the education of women on moral grounds: first, instruction of women by precept rather than reason produces the opposite of the desired result (superstition and immorality instead of right belief and virtue); second, since moral principles are best inculcated in childhood, women, as mothers, have an important role as teachers of their children.

In her letters to Leibniz, Lady Masham takes issue with him on a number of points, among them his concept of 'atomes de substance' - whether unextended substances exist and how free will can be maintained within pre-established harmony. Her most important point relates to her critique of Norris: namely that, if matter is denied a causal role in Leibniz's system, the organization of matter is rendered 'superfluous and lost labour'. Although Lady Masham helped to establish a place for women in philosophy, she accepted limitations on their philosophical

activities: in *Occasional Thoughts* she notes that women should not spend their time in unnecessary speculations, but they should endeavour to improve their minds by more than merely doing their duty.

SARAH HUTTON

List of works

Note on correspondence: Lady Masham's correspondence has not been collected, apart from her letters to Leibniz which have been reproduced in *Die Philosophischen Schriften von Gottfried Wilhelm Leibniz* (ed. C.I. Gerhardt, Berlin: Weidmannsche Buchhandlung, 7 vols, 1875-90, vol. 3, 372) and to Locke in *The Correspondence of John Locke*, (ed. E.S. de Beer, 8 vols, Oxford: Clarendon Press, 1976-, vols. 2 and 3). Letters to Shaftesbury are in the London Public Records Office (PRO 30/24/20, fols. 266-7 and 273-4), while Amsterdam University Library has three letters to Philip van Limborch (MS M31c).

Masham, D. (1696) *A Discourse Concerning the Love of God*, London; French trans. *Discours sur l'Amour Divin*, Amsterdam, 1705.(A critique of *Letters Concerning the Love of God* (1695) by John Norris and Mary Astell.)

Masham, D. (1705) *Occasional Thoughts in Reference to a Vertuous or Christian Life*, London.(The second printing in 1747, *Thoughts on a Christian Life*, was misattributed to Locke.)

Masham, D. (1728) 'Locke, (Jean)', in L. Moreri, *Le Grand Dictionnaire Historique*, nouvelle edition, Paris, vol. 3.(This is a shortened version of a memoir of Locke, now in Amsterdam University Library (Remonstrants MSS J. 57a), which also forms the basis of *Eloge de feu Mr. Locke* by Jean Le Clerc in *Bibliotheque choisie*, vol. 6, 1705, 342-411.)

Mass terms

Mass terms are words and phrases such as 'water', 'wood' and 'white wallpaper'. They are contrasted with count terms such as 'woman', 'word' and 'wild wildebeest'. Intuitively, mass terms refer to 'stuff'; count terms refer to 'objects'. Mass terms allow for measurement ('three kilos of wood', 'much water'); count terms allow for counting, quantifying and individuating ('three women', 'each word', 'that wildebeest over there').

Philosophical problems associated with mass terms include (1) distinguishing mass from count terms, (2) describing the semantics of sentences employing mass terms, and (3) explicating the ontology presupposed by our use of mass versus count terms. Associated with these philosophical issues - especially the third - are the meta-philosophical issues concerning the extent to which any investigation into the linguistic practices of speakers of a language can be used as evidence for how those speakers view 'reality'.

1 Distinguishing mass and count terms

The distinction between mass terms ('water', 'wood' and so on) and count terms ('woman', 'word' and so on) can be seen as syntactic, semantic or pragmatic. If the distinction is seen as syntactic, one might remark that mass terms occur with the quantifiers 'much' and 'little' and with the unstressed article 'some', that they are susceptible to measurement phrases such as 'litres of' and 'amount of', and that they do not exhibit a singular/plural distinction. Conversely, count expressions occur with the quantifiers 'each', 'every', 'many', 'several', 'few' and the stressed 'some', use the indefinite article 'a(n)', are susceptible to counting phrases such as 'five' and 'a score of', and exhibit a singular/plural dichotomy manifested in the count term itself and in agreement with the verb phrase.

If it is seen as semantic - a distinction between the different ways that mass and count terms refer - then one might remark that count expressions refer to discrete, well-delineated objects while mass terms refer without making it explicit how the referent is individuated (some have said that the referents of mass terms are continuous rather than discrete). This feature of mass reference gives rise to the 'cumulative reference test' (any sum of parts which are *M* is also *M*) and to the 'distributive [homogeneous] reference test' (any part of something which is *M* is also *M*).

If the mass/count distinction is seen as a pragmatic one, then one will look to how people use count terms to 'individuate' the world. This gives rise to such tests as whether there is a definite answer to the question 'How many *X*'s are there in such-and-such place?'. In the philosophical literature (following Strawson 1959), terms which pass this counting test are often called 'sortal terms' - although they are equally often called count terms - and ones that fail the test are called mass terms. In this literature, with its emphasis on the pragmatic notions of 'identifying' and 'individuating', it is common to deny that such terms as 'thing', 'object' and so on are sortal (count), there being no definite answer to the question 'How many things are in the room?'. This is so despite the fact that such terms clearly satisfy the syntactic criteria.

All these tests - the syntactic, the semantic and the pragmatic ones - have been challenged. Writers have pointed out that mass terms such as 'wood' can also be used as count: 'a wood' might designate oak or spruce, for example. And 'wildebeest' can be used as a mass term: 'He's not really a vegetarian; he eats wildebeest'. Furthermore, a universal grinder would take an object that an alleged count term referred to - a chair, for example - and grind it up into a powder so that then there would be chair all over the floor. (This last sentence uses 'chair' in a mass manner, thereby showing that the language already has this usage of any count term in the background. And this usage exists despite the fact that we could also have said 'There is wood all over the floor'.)

The criteria just mentioned are usually seen as applying to entire noun phrases as well as to the simple nouns themselves. Furthermore, some writers attempt to apply the mass/count distinction to other syntactic categories, especially adjectives, verbs and adverbs. The application to verbs is especially interesting (see Mourelatos 1978).

2 Semantics and ontology of mass terms

The problem with giving a formal semantic analysis of mass terms arises because first-order predicate logic appears to assume that the entities in the domain of quantification are individuals, so it only makes sense to characterize them with count nouns. When we say, in the quantifier idiom, 'For all *x*, if *x* is *F*…', it is apparently

assumed that the items in the domain have already been individuated. For if *F* were to be interpreted as 'snow', for example, what would be the values of *x*?

Famously, Quine (1960) held that mass terms are ambiguous: when in 'subject position' they are singular terms (names), but when in 'predicate position' they are general terms (predicates) which are 'true of each portion of the stuff in question, excluding only the parts too small to count'. As a name (when in subject position), Quine holds that a mass term 'differs none from such singular terms as "mama"…, unless the scattered stuff that it names be denied the status of a single sprawling object'.

This proposal has not satisfied various authors, who have objected to the nonuniform treatment and to various logical consequences of this approach. For example, on Quine's analysis, 'Water is wet, and this puddle is water' does not imply 'This puddle is wet'; and 'Water is water' does not come out a logical truth. Writers after Quine have proposed many different approaches. Possibly the most popular alternatives involve mereology, according to which the main operator is 'is a part of'. Mass (and other) terms are taken to designate 'mereological wholes'. Some authors have grafted onto pure mereology a notion of 'having certain structural properties', so as to avoid the minimal parts problem alluded to in Quine. (The atoms, *inter alia*, which are part of water are 'too small' to count as water.) But these theories also have not satisfied all those involved in this area, usually because the treatment of certain logical inferences is thought incorrect: the formal semantic analyses do not mirror intuitive beliefs concerning logical consequence.

An alternative is to retain the idea that mass terms name some kind of object - a 'substance' - and to invoke a relational predicate such as 'is constituted of'. This presents a number of tricky issues and there are types of sentences for which such an analysis is not obviously suitable, but still various authors have adopted it. Besides the formal differences entailed by these two approaches (mereological calculus of individuals versus classical logic with a relational constant of constitution), there is an ontological difference, for mereological wholes are generally taken to be physical whereas substances or kinds are often viewed as abstract entities (see Substance).

Another formal semantics of mass terms invokes sets as their denotation. Differences among theorists can then be seen as differences about what the sets contain. One question on which theorists differ is whether the sets contain only 'minimal entities' - the smallest items to which the mass term refers (flakes, maybe, for 'snow'; the items and size vary according to the mass term in question) - or whether it should contain 'ordinary objects' (flakes, drifts, snowmen, snowballs and so on; any object which can be said to be snow). The former proposal has not gained many adherents due to the difficulty of specifying a set of 'minimal entities' for such mass terms as 'garbage', 'speed' and 'information'. The latter proposal runs into difficulties in trying to account for the denotation of definite noun phrases (NPs) such as 'the snow on the table'. It is generally not true that there is exactly one snow-thing on the table. (There is one ball and also many flakes making it up, for example.) So the only reasonable proposal is for the NP to designate *all* the snow-things on the table. But then certain measurement sentences - for example, 'The snow on the table weighs one kilo' - come out wrong, since we will count the same snow-entities many times over.

Theories of mass terms show a fundamental division between those that are committed to abstract substances and those that are physicalistic in nature, invoking mereological wholes. On the physicalistic side are those theories which propose that the ontologically basic objects are the minimal entities, those which claim that the larger entities are 'constructions' out of these minimal entities, and those theories which propose that all these entities are equally basic. On the other side of the gulf are the various styles of substance theories, which usually invoke a lattice structure of kinds. Such ontological issues are discussed in Pelletier and Schubert (1989) and in Burkhardt and Smith (1991).

(1985) *A Comprehensive Grammar of Contemporary English*, London: Longman.(The most thorough descriptive account of the grammar of the English language, with a section about the mass/count distinction, especially as it is used in normal speech. It does not deal particularly with the formal semantics of the distinction.)

Strawson, P.F. (1959) *Individuals: An Essay in Descriptive Metaphysics*, London: Methuen.(It is here that the distinction between ‘feature-placing universal’ and ‘sortal universal’ was drawn. Many writers wished to put mass terms in the former category, giving rise in the philosophical literature to the opposition ‘mass/sortal’. Other writers thought of mass terms as a type of sortal term, while still others argued for a third category.)

Materialism

Materialism is a set of related theories which hold that all entities and processes are composed of - or are reducible to - matter, material forces or physical processes. All events and facts are explainable, actually or in principle, in terms of body, material objects or dynamic material changes or movements. In general, the metaphysical theory of materialism entails the denial of the reality of spiritual beings, consciousness and mental or psychic states or processes, as ontologically distinct from, or independent of, material changes or processes. Since it denies the existence of spiritual beings or forces, materialism typically is allied with atheism or agnosticism.

The forms of materialism extend from the ancient Greek atomistic materialism through eighteenth- and nineteenth-century scientifically based theories, to recent sophisticated defences of various types of materialism.

1 Materialism

Materialism is the general theory that the ultimate constituents of reality are material or physical bodies, elements or processes. It is a form of monism in that it holds that everything in existence is reducible to what is material or physical in nature. It is opposed to dualistic theories which claim that body and mind are distinct, and directly antithetical to a philosophical idealism that denies the existence of matter. It is hostile to abstract objects, if these are viewed as more than just a manner of speaking (see Abstract objects). An implication of materialism is that the diverse qualitative experiences we have are ultimately reducible to quantitative changes in objects or in our physiological functioning. All the properties of things, including persons, are reducible to properties of matter. Although the terms referring to psychic states such as intention, belief, desire and consciousness itself have a different sense and use than terms referring to material events, a consistent materialist would deny that mentalistic terms have reference to anything other than physical events or physiological changes in our brains. The enormous advances in the sciences have contributed storehouses of empirical data that are often used to support materialism. Many philosophers have been attracted to materialism both because of its reductive simplicity and its association with scientific knowledge.

2 Ancient Greek atomism

Although Leucippus is credited with inventing the atomic theory of matter in the fifth century BC, it was Democritus (fourth century BC) who developed a systematic theory of atomistic materialism. This theory states that matter is composed of separate and minute elements that are ‘uncuttable’ (*atoma*), that these elements move in empty space or the ‘void’. Atoms differ only in shape and volume, and all change occurs by the transfer through direct contact of movement from atoms in motion. These elementary entities are lacking in secondary qualities and are indestructible. Democritus held that things are hot or cold, sweet or bitter, or have different colours ‘by convention’. In reality, ‘there are atoms and the void’.

The essentials of early atomism were retained in Epicurus’ physics, with the exception that Epicurus ascribed freedom to atoms in their movement through space. Epicurean materialism is lucidly expressed in the philosophic poem by Lucretius, *De rerum natura (On the Nature of Things)*, in the first century BC. This popularization of Epicurean thought did much to keep alive both atomistic materialism and what is already recognizable as a naturalistic understanding of humans and world (see Epicureanism).

3 Modern materialism

During the first half of the seventeenth century the atomistic materialism of the Greco-Roman period was revived in a paradoxical way by Pierre Gassendi. He appreciated the scientific interpretation of nature and the methods of science but, at the same time, preserved the Christian idea of the immortality of the soul and conceived of God as the creator of the atoms. The English philosopher Thomas Hobbes presented a systematic theory of nature and human nature that was largely, though not completely, materialistic. Apart from attributing ‘drive’ or *conatus* to human action and sensation, Hobbes virtually banished the concept of ‘incorporeal substance’. In theory and sentiment Hobbes was a materialist thinker, although not a consistent one. The early eighteenth century saw the publication of the first of many works that defended a materialistic and mechanistic interpretation of mankind’s nature on the basis of physiological theory. In *L’Homme machine* (1748) Julien de La Mettrie, a philosophical

physician, described human beings as self-moving mechanisms and sought a neurological basis for mental activity. An advance on previous attempts to develop a systematic materialism is Paul H.D. d'Holbach's 1770 *Système de la nature (The System of Nature)*. Here, a consistent naturalistic materialism is expounded in that cognitive and emotive states are reduced to internal material 'modifications of the brain'. Though not calling it such, d'Holbach presents a form of physiological determinism.

With the rapid growth of the sciences, the astronomical discoveries of Copernicus, the theories of Galileo, and the systematic conception of nature in the physical theory of Isaac Newton, naturalistic interpretations of a variety of phenomena became more and more prevalent. This scientifically founded picture of reality lent greater plausibility to the principles of materialistic theory. The astronomer and mathematician Pierre Laplace (1749-1827) produced a sophisticated astronomical theory which, he thought, illustrated that a supermind, knowing all the states and conditions of every existing entity, could predict the total state of the cosmos in the next moment. When Napoleon I was shown a copy of Laplace's work, he is supposed to have commented on the absence of any mention of God. Laplace replied, 'I have no need of that hypothesis'. Laplace's mechanistic materialism became, in the hands of many thinkers, the definitive explanatory principle of all events.

The formulation of the biological theory of evolution by means of natural selection by Charles Darwin virtually eliminated teleological explanations of biological phenomena and thereby buttressed material and physical interpretations of organic development. With the advances in chemistry achieved by Lavoisier (1743-94) in France and John Dalton (1766-1844) in England, the reductive analysis of natural phenomena to chemical substances, elements and processes bolstered the empirical, naturalistic and materialistic interpretations of phenomena. During the nineteenth century many philosophical thinkers sought to build theories on the foundation of scientific facts, principles or laws. The historical materialism developed by Marx and Engels sought to formulate laws of social, economic and historical development, but did not defend metaphysical materialism (see Dialectical materialism). The general appeal of materialism in the nineteenth century is shown by the popularity of the 1855 work by Ludwig Büchner, *Kraft und Stoff (Force and Matter)*, which passed through sixteen editions. Although philosophically crude, it is an accessible compendium of popular materialism. In 1852, Jacob Moleschott had defended the reduction of force to matter, the doctrine of the conservation of matter, and a species of objective relativism in *Der Kreislauf des Lebens (The Cycle of Life)*. Following the ill-chosen analogy between the brain and thought and the digestive system in Jean Cabanis' *Rapports due physique et du moral de l'homme (Relations of the Physical and the Mental in Man)* (1802), Karl Vogt proclaimed that the brain 'secretes' thought the way the liver secretes bile. Despite such excursions into 'vulgar materialism', the nineteenth century became a period of intense debate for scientists and philosophers alike in regard to the limits of scientific knowledge and the epistemological problems of metaphysical materialism. This was fuelled by a Neo-Kantian movement which, particularly in *Geschichte des Materialismus (History of Materialism)* (1865) by F.A. Lange, held that materialism is a useful methodological principle in science, but questionable as a reductionist metaphysics. The concepts and postulates of science are theoretical entities or conventional notions formed by the mind. Their usefulness does not, according to Lange, warrant their role as bases for materialism.

4 Recent materialism

In the twentieth century, physicalism has emerged out of positivism. Physicalism restricts meaningful statements to physical bodies or processes that are verifiable or in principle verifiable. It is an empirical hypothesis that is subject to revision and, hence, lacks the dogmatic stance of classical materialism. Herbert Feigl defended physicalism in the USA and consistently held that mental states are brain states and that mental terms have the same referent as physical terms (Feigl 1958). The twentieth century has witnessed many materialist theories of the mental, and much debate surrounding them (see Behaviourism, analytic; Functionalism; Mind, identity theory of; Materialism in the philosophy of mind).

In the field of artificial intelligence, the mind is held to be analogous to computers in so far as it functions as an information-processing entity. Daniel Dennett has, in a qualified way, argued that information-processing machines are valid models of the mind. In addition to the scientifically informed arguments for various forms of materialism, including nonreductive materialism, the twentieth-century conception of matter as composed of electrons, protons and other subatomic particles has spawned a rich speculative literature that effectively undermines previous forms of materialism. What the late US philosopher of science, Norwood Hanson, called the

'dematerialization' of matter, raises questions concerning what 'materialism' means in terms of the theories of microphysics. Many of the arguments that sustained earlier forms of materialism (including the assumption of causality as universal in nature) have been put in question. The confluence of contemporary theories about the structure and function of the mind and the nature of matter have introduced a complexity of detail and an array of paradoxical claims that make contemporary materialism a welter of intriguing, but conflicting and perplexing, theoretical elements.

Materialism in the philosophy of mind

Materialism - which, for almost all purposes, is the same as physicalism - is the theory that everything that exists is material. Natural science shows that most things are intelligible in material terms, but mind presents problems in at least two ways. The first is consciousness, as found in the 'raw feel' of subjective experience. The second is the intentionality of thought, which is the property of being about *something beyond itself; 'aboutness' seems not to be a physical relation in the ordinary sense.*

There have been three ways of approaching these problems. The hardest is eliminativism, according to which there are no 'raw feels', no intentionality and, in general, no mental states: the mind and all its furniture are part of an outdated science that we now see to be false. Next is reductionism, which seeks to give an account of our experience and of intentionality in terms which are acceptable to a physical science: this means, in practice, analysing the mind in terms of its role in producing behaviour. Finally, the materialist may accept the reality and irreducibility of mind, but claim that it depends on matter in such an intimate way - more intimate than mere causal dependence - that materialism is not threatened by the irreducibility of mind. The first two approaches can be called 'hard materialism', the third 'soft materialism'.

The problem for eliminativism is that we find it difficult to credit that any belief that we think and feel is a theoretical speculation. Reductionism's main difficulty is that there seems to be more to consciousness than its contribution to behaviour: a robotic machine could behave as we do without thinking or feeling. The soft materialist has to explain supervenience in a way that makes the mind not epiphenomenal without falling into the problems of interactionism.

1 From epiphenomenalism to functionalism

Would-be materialists in the latter part of the nineteenth century tended to be epiphenomenalists. They believed that the world was a physical machine, but felt obliged to concede that examination of its machinery, however minute, could never uncover nor explain consciousness. Consciousness was, therefore, an inexplicable left-over (see Epiphenomenalism). Materialism in the twentieth century has largely been concerned to provide a more integrated form of physicalism. The attempt has taken 'hard' and 'soft' forms.

The source of all forms of contemporary hard materialism is behaviourism, which identifies mental states with facts about how people are disposed to respond to external stimuli (see Behaviourism, analytic). The essence of mind is not, therefore, something private to the subject, but something public and observable, a logical product of the relation of stimulus to response. Two fundamental problems plague behaviourism. A phenomenological objection is that we can supposedly tell just from being conscious that experience is more than a mere disposition to behave. A formal objection is that one cannot give necessary and sufficient conditions for being in a given mental state solely in terms of stimulus and response. Behaviourists treated the brain as a 'black box' about which the psychologist must not speculate, but the interdependence of our mental states so complicates the relation of stimulus to response that this relation can only be understood with the aid of a model of our inner workings.

The identity theory of mind, which emerged from Australia in the work of J.J.C. Smart (1959) and D.M. Armstrong (1968), was designed to cope with both problems (see Mind, identity theory of). Armstrong accepted that mental states were dispositions, but identified these, not with abstract relations between stimulus and response, but with the states of the brain that tend to be caused by the appropriate stimulus and to cause the relevant behavioural response. This identifies experience with something occurrent and actual as well as with a disposition. Moreover, by identifying the mind with a complex internal neural structure, it allows mental states to be specified, *not* by any direct relation to stimulus and response but by a complex profile that relates them to stimulus, response *and* all the other mental states that might interact or interfere with their operation.

This theory was influenced by the development of computers and artificial intelligence (see Artificial intelligence). At first, identity theorists had tended to adopt *type identity*, according to which pain, or imagining the Eiffel Tower, would be identical with the same kind of brain state in every creature with these mental states. It was then argued both that such type identity was implausible and that it was not necessary: just as the same programme can be run on different hardware, the same network of causal relations that constitute the mind could be realized in

differently built brains. This is the theory known as functionalism, according to which there is, at most, a token identity between brain and mental states; that is, each mental state is identical with some brain state or other (see Functionalism). Some functionalists prefer to weaken the relation further by talking of the mind being *realized in* the brain rather than being identical to it.

2 Functionalism and consciousness

Functionalism is, therefore, either with or without token identity, that development from - or, perhaps, that developed form of - behaviourism, which is designed to give serious weight to inner processes. However, it faces many problems. It is questionable whether functionalism is phenomenologically any better than normal behaviourism. This doubt is expressed in a group of qualia problems, such as the ‘inverted qualia’ and ‘absent qualia’ problems. But the essence of ‘qualia’ worries seems to have become distilled in the ‘knowledge argument’ (see Qualia). Take someone lacking a certain sensible capacity from birth - they are completely deaf, for example. Suppose, too, that they have learned all that a completed physical science could tell them about the physical processes and the functional organization of the hearing mechanism: call them ‘the Deaf Scientist’. Third, suppose that they then gain their hearing. They would then gain some new knowledge, namely *what it is like to hear*, or *what sound is experientially like*. As they knew all the physical and functional information before, this kind of knowledge must concern something over and above the physical and functional; so the content of experience is something over and above the physical and functional.

Various strategies can be tried against this argument. First, one might argue that if the Deaf Scientist really did know all the physical and computational information about how hearing worked, they would know what sounds sound like. But this seems wrong, because a deaf person could not work this out from current science - more of the same physical and computational information (or the same in greater detail, which could be what a completed science gives), does not seem to be the right kind of thing to tell you what the actual experience of hearing is like. So, second, one might argue that what the formerly Deaf Scientist acquires when they find out what sound sounds like is not new knowledge, but a new way of getting a kind of knowledge they already possess; perception and science give you the same information, one directly through the senses, the other in a propositional form. So the difference is like that between getting the information that Tom is bald by seeing him and getting it by reading about him. But neither does this seem right, for though the Deaf Scientist does indeed acquire a new way of getting knowledge when they gain their hearing, they also gain knowledge of what it is like to hear. If this is not to be new knowledge, it would have to be just the same knowledge as they have as a scientist when they know about the relevant brain process, and this it does not seem to be.

At least it is clear that the knowledge they gain by hearing is not cast in the same neurological terms as the scientific information they already knew, so at least new concepts are involved. Does this imply that new information is acquired? It has been suggested that the necessity for different concepts need not mean that what is being presented are different properties of, or different facts about, the world. The same property or situation is presented in different ways, as when two concepts have the same property as reference while having different senses (for example, ‘blue’ and ‘the colour of the sky’ present the same feature of the world). But unless there is some reductive analysis of how the mental concepts capture the physical properties, such as the functionalist would provide, it is difficult to see why there should be need for new concepts to capture experience, unless it were that they captured different properties from those caught by the physical vocabulary.

Adopting a functionalist account of the mentalistic concepts that actual hearing calls into play is equivalent to admitting that the Deaf Scientist acquires only a kind of ‘knowledge how’ on coming to hear - that is, they come to be able to respond directly to sounds. This toughly neo-behaviourist view is sometimes seemingly alleviated by saying that what the Deaf Scientist comes to learn is how to imagine, or how to remember, the experience. This does not appear too harshly reductive, for what they come to be able to do does not appear to be mere behaviour. But that is only because we still need an account of the mentalistic notions of imaging, and of remembering what an experience was like: taking images (memory or otherwise) as basic is no different from taking ‘raw feels’ as basic. But if these notions are treated in functionalist terms, being finally explained in terms of an ability to say and outwardly do certain things, then the response has become totally reductive and will not convince anyone who thought there was a problem for the functionalist in the first place.

3 Functionalism and matter

It is a largely unexamined assumption of late twentieth-century materialists that the concept of matter, unlike that of mind, is unproblematic. Some philosophers, however, have followed Russell and argued that the conception of the physical world given to us by science is purely functional and formal: science, that is, tells us nothing about the intrinsic nature of anything, only about its behaviour and how to quantify it, and that this alone is an inadequate conception. Qualitative content is given to our conception of the world from the qualia presented in perception, and without that there would be no non-relational and non-formal content to our conception of the world. But functionalism denies that qualia are given in experience and presents the same kind of purely relational conception of experiential states as physical science does of the physical world. If functionalism is correct, we are stuck with a conception of the world which is entirely relational, with no intrinsic content to any of the relata. This may be an incoherent conception.

4 Alternatives to functionalism

One response to the problems faced by these reductive styles of materialism is to abandon the attempt to reduce mental properties and to admit a *dualism* of properties, while prescribing that the mental *supervenes* on the physical in such a tight way that the spirit of materialism is preserved (see Supervenience). This tightness would mean that the dependence was more than merely causal, without being analytic, in the way a reductive account would require.

The first problem this theory faces is to give a proper rationale for supervenience. The provision of a simple definition is easy: the mental supervenes on the physical if there cannot be a mental difference or change without a physical difference or change, and the ‘cannot’ depends on something stronger than a natural law. The problem comes in explaining what this stronger-than-natural necessity is, and why one should believe in it. No generally acceptable account of this seems to have been found. Furthermore, the question remains of whether the matter of the brain is influenced in its behaviour by the supervenient mind. If it is, then the physical system is being influenced by something not itself physical, and this is a species of interactionism. If it is not influenced, then the mind is an epiphenomenon. However, twentieth-century materialism had sought to avoid both interactionism of this kind and epiphenomenalism (see Epiphenomenalism).

There is another and entirely opposite response to the difficulties of functionalism in accommodating the apparent data of thought and experience, and that is to deny that there are any such data. Various traditions came together to bear exotic fruit: the pragmatist doctrine that one should believe whatever is most convenient overall; the post-positivist tendency to deny the distinction between observation and theory; Wittgenstein’s polemic against private data, produce the doctrine that nothing is so plainly revealed in everyday experience that it cannot be overridden by requirements of scientific elegance. Even the seemingly most obvious facts of experience are actually theoretical speculations and can be denied if science is thereby made easier (see Eliminativism; Pragmatism; Private language argument).

Two conceptions of theory seem to be operating in such eliminativism, and they may not always be clearly distinguished. According to one, a theory is any generalization that can be used to provide explanations; according to the other, a theory is something not so blatantly obvious as to be free from revision. This latter, of course, goes naturally with the observation-theory distinction that the eliminativist rejects. But there are many explanatory principles that are totally beyond revision; for example, that wood generally floats, that pigs cannot fly and that cutting off someone’s head kills them. Any higher-order theory that contradicted any of these would be false. Perhaps the use of the term ‘folk psychology’ to characterize our normal psychological generalizations makes them seem more like folklore - more like the belief that comfrey boiled in holy water relieves rheumatism - than they are like the belief that pigs cannot fly. It seems plausible, however, that the law that we shout out because of pain, or eat because we feel hungry, belongs more with the pigs than the comfrey.

5 Cognitive science and intentionality

The development of Artificial Intelligence tended to switch philosophers’ attention from sensation to cognition and, hence, to intentionality. The assumption has been that human behaviour is driven by computational activity in the brain. Two kinds of question have been raised. The first concerns the relation between this computation and the ordinary psychological explanations that we give of behaviour - rather coyly described as ‘folk psychology’ (see

§4 above; Folk psychology; Reductionism in the philosophy of mind). The other is more directly concerned with the problem intentionality poses for materialism. The language of a computer program works entirely as a formal syntax, and brain states, considered simply as biochemical, have no intrinsic meaning; how, then, does neural computation come to have semantic content? Everyone seems to agree that it must be in virtue of the functional relations inner representations have to their typical causes and their behavioural effects, possibly considered in relation to the wider environment and the evolutionary process that produced them (see Functionalism §7). The details of this functional account are disputed, but the main problem is that it is entirely externalist (see Content: wide and narrow). If one thinks of consciousness as something that goes on 'in the head', and that one's own consciousness of one's thoughts is consciousness of one's internal representations, and if those representations have meaning because of the *external* relations they stand in to the world outside the head, then it looks as if consciousness will not reveal to one the contents of any of one's thoughts, nor, indeed, of any kind of mental representation. For all purposes, we will be in the situation of Searle in his 'Chinese room', inspecting symbols we do not understand (see Chinese room argument).

Tyler Burge (1988) has tried to answer this objection to externalism. He says that the holding of the external relations is an *enabling condition* for the representation to have meaning, but that knowing something - in this case the meaning - does not involve explicit knowledge of all the enabling conditions. So we can know the contents of our own thoughts although we do not know the relations that give them their content. The problem with this reply is that, although it is true that we do not, in general, need to know all the things that make something possible in order to know the thing itself, the external relations seem not to be just enabling conditions, but to constitute the content itself. Searle's thought experiment seems to show how ignorance of them actually constitutes ignorance of the meaning of the representations.

6 Materialism and abstract objects

Although materialists are mainly concerned with problems that flow from the philosophy of mind, abstract objects constitute a much less discussed but serious problem. If one believes that it is an irreducible fact that there are any or all of numbers, universals, properties, sets or propositions, then one believes there are things which are not material particulars. It might be that one did not mind adding such light baggage as abstract objects to one's otherwise materialist ontology; but if there are such things as universals and propositions, it looks as if they must enter intimately into our thinking, or, if numbers, into our counting. This would then create a problem for giving a materialist account of these activities, and so accepting abstract objects might have consequences for the philosophy of mind (see Abstract objects).

7 Materialism at the *fin de siècle*

The materialist mood in the twentieth century has been poised between an almost triumphalist self-confidence and a more modest perplexity. The triumphalism is produced by the success of science, which makes materialism seem obviously true. In this mood, materialists are prepared to deny what seem to be the most obvious facts of mental life if their theory requires it. In a more sombre moment, however, some will confess that all attempts to tackle the problems have so far missed the mark. This more sober tendency became stronger in the 1980s and 1990s. Nagel (1974) had already declared that the mind-body problem could only be solved by a conceptual breakthrough we could not, as yet, imagine. McGinn (1991) pronounced the problem insoluble in principle because the mind cannot understand itself. Galen Strawson (1994) has denied that there is any conceptual connection between mind and behaviour. All these philosophers deem themselves to be materialists, of some not-yet-quite-articulable kind. The *Journal of Consciousness Studies* has been set up to 'take consciousness seriously' in a way it is said science has not so far done; but perhaps this underestimates the main reason why consciousness has been sidelined and treated harshly: namely because it seems so clearly impossible to say anything constructive about it within the materialist presuppositions of natural science.

Materialism, Indian school of

'Materialism' stands here for the Sanskrit term Lokāyata, the most common designation for the materialistic school of classical Indian philosophy. However, at the outset 'materialism' and 'Lokāyata' were not equivalent: early materialistic doctrines were not associated with Lokāyata, and early Lokāyata was neither materialistic nor even a philosophical school.

Classical Lokāyata stands apart from all other Indian philosophical traditions due to its denial of ethical and metaphysical doctrines such as karmic retribution, life after death, and liberation. Its ontology, tailored to support this challenge, allows only four material elements and their various combinations. Further support comes from Lokāyata epistemology: the validity of inference and Scriptures is denied and perception is held to be the only means of valid cognition. As offshoots, a fully fledged scepticism and a theory of limited validity of inference developed in response to criticism by other philosophers. Consistent with Lokāyata ontology and epistemology, its ethics centres on the criticism of all religious and moral ideals which presuppose invisible agents and an afterlife. Hostile sources depict its followers as promulgating unrestricted hedonism.

1 Sources

With the single exception of Jayarāśi's *Tattvopaplavasiṃha*, no original Lokāyata works have survived. Our knowledge of Lokāyata is based mainly on fragments and references in often hostile and polemic Brahmanical, Buddhist and Jaina sources. Of the basic text of the materialistic Lokāyata, the *Bṛhaspatisūtra*, only a few fragments remain. Therefore doxographies are of particular importance for our impression of the philosophical system as a whole. Unfortunately, it is not certain to what extent these and other sources represent genuine Lokāyata doctrines. As it was the only philosophical school to deny rebirth and karmic retribution, it was criticized by all other schools. However, many of these refutations are perfunctory and do not add substantially to our knowledge.

2 Lokāyata in early sources

In the earliest references, found in the Buddhist Pāli canon (first committed to writing in the first century BC), Lokāyata designates a Brahmanical branch of learning concerned with the examination of fundamental statements about the nature of the world (equally called *lokāyata*). The *Saṃyuttanikāya* of the Pāli canon mentions four *lokāyatas*: (1) All exists; (2) All does not exist; (3) All is unity; (4) All is severalty. Such pairs of theses and antitheses were topics of public philosophical debate. A later Mahāyāna text, the *Laōkāvatārasūtra*, mentions no fewer than thirty-one *lokāyatas* on topics such as the world, the soul, life after death, liberation (*mokṣa*), momentariness, space, the state between death and birth, and ignorance, desire and karma as causes of the world. Some of them are easily recognized as points of debate among various Hīnayāna Buddhist schools. A connection to materialism is not evident in these sources, nor in another early reference, in the *Arthaśāstra*, which subsumes Lokāyata under those branches of learning which proceed by or are concerned with reasoned investigation (see Kauṭilya). By the second century BC there existed a Lokāyata commentary of unknown content by a certain Bhāguri.

3 Early materialists

The ascetic Ajita Keśakambala (Ajita Kesakambali) was a renowned teacher and contemporary of the Buddha, nicknamed after a blanket made of hair (*keśakambala*) which kept him hot in summer and cold in winter. He maintained that man consists of the four elements earth, water, fire and wind, and that after death his constituents return to the respective elementary mass: what is of earth goes to earth, what is of water to water, and so on; his senses join space. There is no afterlife. Thus sacrificial and moral works, good or bad, do not bear any fruit.

Materialism flourished also at kingly courts. Both the Jaina and Buddhist canons report the views and gruesome experiments of King Paesi (Pāyāsi), who argued that if the soul were different from the body and if a person's fate after death depended on deeds in this life, deceased relatives could be expected to come back from the other world to warn and admonish those left behind. He once had a thief condemned to death put into a hermetically sealed and guarded jar. The prisoner was found dead after a while and the escape of a soul was not observed. On another occasion, Paesi had an executed thief placed in a sealed jar. The jar was later found full of worms, although their

souls could not have entered it. Weighing immediately before and after death and dissection of bodies did not yield evidence for the existence of a soul.

It is noteworthy that both the legendary founder of Lokāyata and the founder of a school of political science (*arthaśāstra*) bear the name Bṛhaspati. It is quite possible, though not yet provable, that Indian materialism developed in kingly and state administration circles as an alternative worldview counterbalancing that of the priestly class.

4 The classical materialistic philosophy

From at least as far back as the sixth century AD onwards, Lokāyata is referred to as a materialistic philosophical school. Its followers, the Lokāyatas or Lokāyatikas/Laukāyatikas, are also called Bārhaspatyas (followers of Bṛhaspati) and Cārvākas. These terms seem to apply only to the followers, not to the school itself. Some modern authors assume a subdivision into 'well-instructed' (*suśikṣita*) and 'cunning' (*dhūrta*) Cārvākas; however, both appellations refer mockingly to the Cārvāka philosopher Udbhaṭa. The designation *nāstika* (nihilist, one who says '…does not exist') is also applied to the materialists. This broader term is used for those who deny life after death, the efficacy of sacrifices and moral deeds, and so on, as well as for those who do not accept the authority of the Veda. The latter usage includes not only materialists, but also Buddhists and Jainas.

Ontology. According to the *Bṛhaspatisūtra*, there are four 'great' elements, earth, water, fire and wind, although some Lokāyatikas accepted space/'ether' as a fifth element (see Matter, Indian conceptions of §1). Certain Lokāyatikas may have admitted the existence of atoms; the majority, however, denied both atoms and space because they are not perceptible. The world in all its diversity is only the result of various combinations of the material elements. There is no determinative principle, such as God or karma, which is responsible for the properties of things. They are due to their own nature; no agent makes fire hot or water cool. Lokāyata causality operates with material causes only, and efficient causes are not recognized (see Causation, Indian theories of §2).

The theory of elements formed the basis for various Lokāyata doctrines of the arising of consciousness. As stated by the *Bṛhaspatisūtra*, consciousness arises from the elements just as the power of intoxication arises from molasses and other substances when a fermenting agent is added. In other words, when certain material substances are mixed something new emerges, be it consciousness or the power of intoxication, that was not there before and could not be produced by these substances severally. The mixture conducive to the production of consciousness is obtained when the elements are transformed into the form of a body. Later Lokāyatikas, such as Kambalāśvatara, refined this theory by assuming further causal factors that support the body in the production of consciousness, notably the vital breaths and the senses. Strong criticism finally led some Lokāyatikas, probably including Udbhaṭa, to abandon the doctrine that consciousness arises from matter and to conceive it as a different entity. Consequently they admitted that consciousness arises only from consciousness and for the sake of, rather than from, the elements; this reverses the relationship between matter and consciousness as conceived in Sāōkhya, according to which primordial matter evolves for the sake of consciousness (see Sāōkhya §§2, 6). However, these Lokāyatikas did not accept any doctrine of rebirth, but claimed that the consciousness of the new-born arises from that of the parents.

Lokāyata ontology seems to be largely subordinated to the school's ethical agenda. The main aim of all theories of elements and consciousness is to deny rebirth and thereby to destroy the cornerstone of Brahmanical, Buddhist and Jaina socio-religious and ethical ideals that presuppose karmic retribution over many lives (see Karma and rebirth, Indian conceptions of).

Epistemology. Indian epistemological doctrines centre on the pivotal concept of means of valid cognition (*pramāṇa*) (see Epistemology, Indian schools of §2; Knowledge, Indian views of §§1-2). Lokāyata claims that there is only one means of valid cognition: sensory perception. Other means, such as inference and verbal testimony, especially Scriptures, are considered invalid. Undoubtedly their rejection has the purpose of refuting the foundation of social and ethical doctrines in any divine or supernatural power.

The inherent difficulties in this initial Lokāyata position were not immediately apparent. However, once epistemological issues became prominent in Indian philosophy (*circa* fifth century AD), the Lokāyatikas found themselves embarrassed over the justification of their single means of valid cognition. As all other means are denied, perception has to establish itself, which would involve a *petitio principii*, or not be established at all.

Further, it became clear that the theory of four elements could not be established by perception alone; also, the denial of an eternal soul, karma and rebirth, or in fact any denial, cannot be arrived at without some form of reasoning.

At least four responses can be discerned to these challenges. Some Lokāyatikas retained the old doctrine, but developed new arguments against inference. By self-destructive logic they tried to prove that all inferences are invalid. For instance, what is the object of the paradigmatic inference from smoke to fire? If it is the universal 'fire-ness', the inference proves what is already proved, since the universal 'fire-ness' was already known before. If, on the other hand, a particular fire is to be proved, the inference fails because the required concomitance does not obtain between the universal 'smoke-ness' and a particular fire. Another response was to grant inference limited validity to avoid the difficulties of the initial position. A philosopher called Purandara claimed that the Cārvākas also admit inferences, but only those that are well known in everyday practice, such as the one from smoke to fire. Inferences meant to establish nonperceptible entities like God or a soul are rejected. To justify only limited use of inference, Purandara emphasized that inference is not an independent means, but depends on perception and therefore cannot transgress the scope of perception. A third response led to the acknowledgement of the indefensibility of perception and a coherent sceptical position. Jayarāśi, whose *Tattvopaplavasiṃha* is the only surviving Lokāyata text, preferred to give up perception rather than to admit the validity of inference. Epistemologically this position is irrefutable, but a high price has to be paid for it. If no means of valid cognition is accepted, the Lokāyata theories of elements and consciousness can no longer be maintained. Jayarāśi accepted this consequence and reinterpreted these doctrines of the *Bṛhaspatisūtra* as the opinions of an opponent that have to be rejected in the final analysis. As an anonymous fragment puts it, the sole purpose of the *sūtras* of Bṛhaspati is to question the opinions of others, and not to establish anything. As a fourth response, Udbhaṭa claimed that the number and characteristics of means of valid cognition cannot be determined. To substantiate his view he adduced examples of knowledge which cannot be derived from any of the recognized means of valid cognition.

Ethics. We are better informed about what Lokāyata condemns than what it prescribes. Many of the reported statements are directed against the efficacy of sacrifices. For instance, if the sacrificed animal goes to heaven, why does the sacrificer not put his own father in its place? The entire Vedic ritual is but a scheme of the Brahmans to make an easy living. Further statements on ethical issues are equally based on the denial of what is imperceptible, notably a transmigrating entity different from the body, an afterlife and the results of one's moral deeds. Thus, among the four 'aims of life' the Lokāyatikas admit only one: pleasure. Sometimes they also consider wealth, as a means to pleasure, to be a legitimate goal; however, the religious and soteriological aims, *dharma* and liberation (*mokṣa*), are always denied (see Duty and virtue, Indian conceptions of §§1-3). No merit or demerit accrues from one's actions; there is neither heaven nor hell and death is the ultimate release. Accordingly, the Lokāyatikas are often described as hedonists. As long as one lives, they say, one should live happily. One should eat meat, drink spirits and indulge in sexual pleasures. That people have an unequal share of pleasure and pain is not due to any unseen force like karma, but to the different capacities of things caused by different combinations of the elements, just as bubbles on the ocean display a diversity of size, hue and duration.

Mathematics, foundations of

Conceived of philosophically, the foundations of mathematics concern various metaphysical and epistemological problems raised by mathematical practice, its results and applications. Most of these problems are of ancient vintage; two, in particular, have been of perennial concern. These are its richness of content and its necessity. Important too, though not so prominent in the history of the subject, is the problem of application, or how to account for the fact that mathematics has given rise to such an extensive, important and varied body of applications in other disciplines.

The Greeks struggled with these questions. So, too, did various medieval and modern thinkers. The ideas of many of these continue to influence foundational thinking to the present day.

During the nineteenth and twentieth centuries, however, the most influential ideas have been those of Kant. In one way or another and to a greater or lesser extent, the main currents of foundational thinking during this period - the most active and fertile period in the entire history of the subject - are nearly all attempts to reconcile Kant's foundational ideas with various later developments in mathematics and logic.

These developments include, chiefly, the nineteenth-century discovery of non-Euclidean geometries, the vigorous development of mathematical logic, the development of rigorous axiomatizations of geometry, the arithmetization of analysis and the discovery (by Dedekind and Peano) of an axiomatization of arithmetic. The first is perhaps the most important. It led to widespread acceptance of the idea that space was not merely a Kantian 'form' of intuition, but had an independence from our intellect that made it different in kind from arithmetic. This asymmetry between geometry and arithmetic became a major premise of more than one of the main 'isms' of twentieth-century philosophy of mathematics. The intuitionists retained Kant's conception of arithmetic and took the same view of that part of geometry which could be reduced to arithmetic. The logicists maintained arithmetic to be 'analytic' but differed over their view of geometry. Hilbert's formalist view endorsed a greater part of Kant's conception.

The second development carried logic to a point well beyond where it had been in Kant's day and suggested that his views on the nature of mathematics were in part due to the relatively impoverished state of his logic. The third indicated that geometry could be completely formalized and that intuition was therefore not needed for the sake of conducting inferences within proofs. The fourth and fifth, finally, provided for the codification of a large part of classical mathematics - namely analysis and its neighbours - within a single axiomatic system - namely (second-order) arithmetic. This confirmed the views of those (for example, the intuitionists and the logicists) who believed that arithmetic had a special centrality within human thinking. It also provided a clear reductive target for such later anti-Kantian enterprises as Russell's logicism.

The major movements in the philosophy of mathematics during this period all drew strength from post-Kantian developments in mathematics and logic. Each, however, also encountered serious difficulties soon after gaining initial momentum. Frege's logicism was defeated by Russell's paradox; Russell's logicism, in turn, made use of such questionable (from a logicist standpoint) items as the axioms of infinity and reduction. Both logicism and Hilbert's formalist programme came under heavy attack from Gödel's incompleteness theorems. And finally, intuitionism suffered from its inability to produce a body of mathematics comparable in richness to classical mathematics.

Despite the failure of these non-Kantian programmes, however, movement away from Kant continued in the mid- and late twentieth century. From the 1930s on this has been driven mainly by a revival of empiricist and naturalist ideas in philosophy, prominent in the writings of both the logical empiricists and the later influential work of Quine, Putnam and Benacerraf. This continues as perhaps the major force shaping work in the philosophy of mathematics.

1 Kant's views; reactions

The '*Problematik*' that Kant established for the epistemology of pure mathematics focused on the reconciliation of two apparently incompatible features of pure mathematics: (1) the problem of necessity, or how to explain the apparent fact that mathematical statements (for example, statements such as that $1 + 1 = 2$ or that the sum of the interior angles of a Euclidean triangle is equal to two right angles) should appear to be not only true but

necessarily true and independent of empirical evidence; and (2) the problem of cognitive richness, or how to account for the fact that pure mathematics should yield subjects as rich and deep in content and method, as robust in growth and as replete with surprising discoveries as the history of mathematics demonstrates.

In mathematics, Kant said, we find a ‘great and established branch of knowledge’ - a cognitive domain so ‘wonderfully large’ and with promise of such ‘unlimited future extension’ that it would appear to arise from sources other than those of pure unaided (human) reason (1783: §§6, 7). At the same time, it carries with it a certainty or necessity that is typical of judgments of pure reason. The problem, then, is to explain these apparently conflicting characteristics. Kant’s explanation was that mathematical knowledge arises from certain standing conditions or ‘forms’ which shape our experience of space and time - forms which, though they are part of the innate cognitive apparatus that we bring to experience, none the less shape our experience in a way that goes beyond mere logical processing.

To elaborate this hypothesis, Kant sorted judgments/propositions in two different ways: first, according to whether they required appeal to sensory experience for their justification; and, second, according to whether their predicate concepts were ‘contained in’ their subject concepts. A judgment or proposition was ‘a priori’ if it could be justified without appeal to sensory content. If not, it was ‘a posteriori’. It was ‘analytic’ if the very act of *thinking* the subject concept contained, as a constituent part, the *thinking* of the predicate concept. If not, it was either false or ‘synthetic’. In synthetic a priori judgment - the type of judgment Kant regarded as characteristic of mathematics - the predicate concept was thought not through the mere *thinking* of the subject concept, but through its ‘construction in intuition’. He took a similar view of mathematical inference, believing it to involve an intuition that goes beyond the mere logical connection of premises and conclusions (1781/1787: A713-19/B741-7).

Kant erected his mathematical epistemology upon these distinctions and, famously, maintained that mathematical judgment and inference is synthetic a priori in character. In this way, he intended to account for both the necessity and cognitive richness of mathematics, its necessity reflecting its a priority, its cognitive richness its syntheticity.

Kant applied this basic outlook to both arithmetic and geometry (and also to pure mechanics). He did not regard them as entirely identical, however, since he saw them as resting on different a priori intuitions. Neither did he see them as possessing precisely the same universality (1781/1787: A163-5, 170-1, 717, 734/B204-6, 212, 745, 762). None the less, he regarded their similarities as more important than their differences and therefore took them to be of essentially the same epistemic type - namely, synthetic a priori. In the end, it was this inclusion of geometry and arithmetic within the same basic epistemic type rather than his more central claim concerning the *existence* of synthetic a priori knowledge that gave rise to the sternest challenges to his views.

In the decades following the publication of the first *Critique* (1781/1787), the principal source of concern regarding its views was the growing evidence for and eventual discovery of non-Euclidean geometries. This led many to question whether geometry and arithmetic are of the same basic epistemic character.

The serious possibility of non-Euclidean geometries went back to the work of Lambert and others in the eighteenth century. Building on this work, some - in particular, Gauss (1817, 1829) - stated their opposition to Kant’s views even before the actual discovery of non-Euclidean geometries by Bolyai and Lobachevskii in the 1820s. Gauss’ reasoning was essentially this: number seems to be purely a product of the intellect and, so, something of which we can have purely a priori knowledge. Space, on the other hand, seems to have a reality external to our minds that prohibits a purely a priori knowledge of it. Arithmetic and geometry are therefore not on an epistemological par with one another.

This reasoning became a potent force shaping nineteenth- and twentieth-century foundational thinking. Another such force was the dramatic development of logic and the axiomatic method in the mid- to late nineteenth century and early twentieth century. This included the introduction of algebraic methods by Boole and De Morgan, the improved treatment of relations by Peirce, Schröder and Peano, the replacement of the subject-predicate conception of propositional form with Frege’s more fecund functional conception, and the advances in axiomatization and formalization brought about by the work of Frege, Pasch, Peano, Hilbert and (especially) Whitehead and Russell.

Certain developments in mathematics proper also exerted an influence. Chief among these were the arithmetization

of analysis by Weierstrass, Dedekind and others, and the axiomatization of arithmetic by Peano and Dedekind. Of somewhat lesser importance, though still significant for their effects on Hilbert's thinking, were Einstein's relativistic ideas in physics.

2 Intuitionism

A variety of views concerning the asymmetry of geometry and arithmetic emerged in the late nineteenth and early twentieth centuries. That of the early intuitionists Brouwer and Weyl retained Kant's synthetic a priori conception of arithmetic.

They responded to the discovery of non-Euclidean geometries, however, by denying the a priori status of that part of geometry that could not be reduced to arithmetic by such means as Descartes' calculus of coordinates. They retained, none the less, a type of a priori intuition of time as the basis for arithmetical knowledge (see Brouwer 1913: 127-8). They also emphasized the synthetic character of arithmetical judgment and inference, and sharply distinguished them from logical judgment and inference.

Brouwer described his intuition of time as consciousness of change *per se* - the human subject's primordial inner awareness of the 'falling apart' of a life-moment into a part that is passing away and a part that is becoming. He believed that, via a process of abstraction, one could pass from this basal intuition of time to a concept of 'bare two-oneness', and from this concept to, first, the finite ordinals, then the transfinite ordinals and, finally, the linear continuum. In this way, parts of classical arithmetic, analysis and set theory could be recaptured intuitionistically. (See Brouwer 1907: 61, 97; 1913: 127, 131-2.)

Brouwer thus modified Kant's intuitional basis for mathematics. He also modified his conception of knowledge of existence. Kant believed that humans could obtain knowledge of existence only through sensible intuition. Only this, he believed, had the type of involuntariness and objectivity that assures us that belief in an object is not a mere compulsion or idiosyncrasy of our subjective selves. Like the post-Kantian romantic idealists, however, Brouwer (and Weyl, too) believed as well in knowledge of existence via a kind of 'intellectual intuition' - an intuition carried by a purely internal type of mental construction (1907: 96-7).

The early intuitionists (especially Brouwer and Poincaré) remained Kantian in their conception of mathematical reasoning and took it to be essentially different in character from 'discursive' or logical reasoning. Brouwer believed logical reasoning to mark not patterns in mathematical thinking itself but only patterns in its linguistic representation. It was therefore not indicative of the inferential structure of mathematical thinking itself and had no place within genuine mathematical reasoning *per se*. This was essentially the idea expressed in Brouwer's so-called 'First Act of Intuitionism' (1905: 2, 1981: 4-5).

Thus the early intuitionists (especially Brouwer and Weyl and, to some extent, Poincaré) discarded Kant's view of geometry, revised his conception of arithmetic and existence claims, and preserved his basic stance on the nature of mathematical reasoning and its relationship to logical reasoning. Later intuitionists (for example, Heyting and Dummett) did not keep to this plan. They rejected Brouwer's view of the divide between logical and mathematical reasoning and made a significant place for logic in their accounts of mathematical reasoning. Some of them (Dummett and his 'anti-realist' followers) even went so far as to make the question 'What is the logic of mathematical reasoning?' central to their philosophy of mathematics (see §5 below).

3 Logicism

The view of the logicist Frege (and, to some extent, of Dedekind) accepted Kant's synthetic a priori conception of geometry but maintained arithmetic to be analytic. Russell, another logicist, rejected Kant's views of both geometry and arithmetic (and also of pure mechanics) and maintained the analyticity of both. (See Logicism.)

Frege's logicism differed sharply from intuitionism. First, it differed in the place in mathematical reasoning it assigned to logic. Frege (1884: preface, III-IV) maintained that reasoning is essentially the same everywhere and that even an inference pattern such as that of mathematical induction, which appears to be peculiar to mathematics, is, at bottom, purely logical. Second, it differed in its conception of geometry. Like the early intuitionists, Frege regarded the discovery of non-Euclidean geometries as revealing an important asymmetry between arithmetic and geometry. Unlike them, however, he did not see this as grounds for rejecting Kant's synthetic a priori conception

of geometry (1873: 3; 1884: §89), but rather as indicating a fundamental difference between geometry and arithmetic. Frege believed the fundamental concept of arithmetic - magnitude - to be both too pervasive and too abstract to be the product of Kantian intuition (1874: 50). It figured in *every* kind of thinking and so must, he reasoned, have a basis in thought deeper than that of intuition. It must have its basis in the very core of rational thought itself; the laws of logic.

The problem was to account for the cognitive richness of arithmetic on such a view. How could the ‘great tree of the science of number’ (1884: §16) have its roots in bare logical or analytical ‘identities’? Frege responded by offering new accounts of both the objectivity and the informativeness of arithmetic. The former he attributed to its subject matter - the so-called ‘logical objects’ (§§26, 27, 105). The latter he derived from a new theory of content which allowed concepts to contain (tacit) content that was not needed for their grasp. On this view, analytic judgments could have content that was not required for the mere understanding of the concepts contained in them. Consequently, they could yield more than knowledge of transparent logical identities (§§64-66, 70, 88, 91).

Unlike Kant, then, Frege maintained an important epistemic asymmetry between geometry and arithmetic - an asymmetry based upon his belief that arithmetic is more basic to human rational thought than is geometry. In addition, he departed from Kant in maintaining a realistic conception of arithmetic knowledge despite its analytic character. He saw it as being about a class of objects - so-called ‘logical objects’ - that are external but intimately related to the mind and therefore not the mere expression of standing traits of human cognition. The differences between arithmetical and geometric necessity were to be accounted for by separating the relationship the mind has to the objects of arithmetic from that which it has to the objects of geometry.

Russell’s logicism differed from Frege’s. Perhaps most importantly, Russell did not regard the existence of non-Euclidean geometries as evidence of an epistemological asymmetry between geometry and arithmetic. Rather, he saw the ‘arithmetization’ of geometry and other areas of mathematics as evidence of an epistemological symmetry between arithmetic and the rest of mathematics. Russell thus extended his logicism to the whole of mathematics. The basic components of his logicism were a general methodological ideal of pursuing each science to its greatest level of generality, and a conception of the greatest level of generality in mathematics as lying at that point where all its theorems are of the form ‘*p* implies *q*’, all their constants are logical constants and all their variables of unrestricted range. Theorems of this sort, Russell maintained, would rightly be regarded as logical truths.

Russell’s logicism was thus motivated by a view of mathematics which saw it as the science of the most general formal truths; a science whose indefinables are those constants of rational thought (the so-called logical constants) that have the most ubiquitous application, and whose indemonstrables are those propositions that set out the basic properties of these indefinables (Russell 1903: 8). In his opinion, such a view provided the only precise description of what philosophers have had in mind when they have described mathematics as a necessary or a priori science.

Russell thus accounted for the necessity of mathematics by pointing to its logical character. He accounted for its richness principally by invoking a new definition of syntheticity that allowed all but the most trivial logical truths and inferences to be counted as informative or synthetic. Mathematical truths would thus be logical truths, but they would not, for all that, be analytic truths. Similarly for inferences. An inference would count as synthetic so long as its conclusion was a different proposition from its premises. Cognitive richness was conceived primarily as the production of new propositions from old, and, on Russell’s conception (supposing the criterion of propositional identity to be sufficiently strict), even purely logical inference could produce a bounty of new knowledge from old.

Russell was thus able to account for both the necessity and the cognitive richness of mathematics while making mathematics part of logic. What had kept previous generations of thinkers and, in particular, Kant from recognizing the possibilities of such a view was the relatively impoverished state of logic before the end of the nineteenth century. The new logic, with its robust stock of new forms, its functional conception of the proposition and the ensuing fuller axiomatization of mathematics which it made possible, changed all this forever and provided for the final refutation of Kant. Such, at any rate, was Russell’s position.

4 Hilbert’s formalism

Hilbert accepted the synthetic a priori character of (much of) arithmetic and geometry, but rejected Kant’s account of the supposed intuitions upon which they rest. Overall, Hilbert’s position was more complicated in its

relationship to Kant's epistemology than were those of the intuitionists and logicists. Like Russell, he rejected Kant's specifically mathematical epistemology - in particular, his conception of the nature and origins of its a priori character. Like Russell, too, he rejected the common post-Kantian belief in the epistemological asymmetry of arithmetic and geometry. Hilbert was, however, unique among those mentioned here in endorsing the framework of Kant's general critical epistemology and making it a central feature of his mathematical epistemology. Specifically, he adopted Kant's distinction between the faculty of the understanding and the faculty of reason as the guide for his pivotal distinction between the so-called 'real' and 'ideal' portions of classical mathematics (Hilbert 1926: 376-7, 392).

Hilbert took 'real' mathematics to be ultimately concerned with the shapes or forms (*Gestalten*) of concrete signs or figures, given in intuition and comprising a type of 'immediate experience prior to all thought' (1926: 376-7; [1928] 1967: 464-5). Hilbert proposed this basic intuition of shape as a replacement for Kant's two a priori intuitions of space and time. Like Kant's a priori intuitions, however, Hilbert, too regarded his finitary intuition as an 'irremissible pre-condition' of all mathematical (indeed, all scientific) judgment and the ultimate source of all genuine a priori knowledge (1930: 383, 385).

The genuine judgments of real mathematics were the judgments of which our mathematical knowledge was constituted. The pseudo-judgments of ideal mathematics, on the other hand, functioned like Kant's ideas of reason. They neither described things present in the world nor constituted a foundation for our judgments concerning such things. Rather, they played a purely regulative role of guiding the efficient and orderly development of our real knowledge.

Hilbert did not, therefore, affirm the necessity of either arithmetic or geometry in any simple, straightforward way. Rather, he distinguished two types of necessity operating within both. One, pertaining to the judgments of real mathematics, consisted in the (presumed) fact that the apprehension of certain elementary spatial and combinatorial features of simple concrete objects is a pre-condition of all scientific thought. The other, pertaining to the ideal parts of mathematics, had a kind of psychological necessity, a necessity borne of the manner in which our minds inevitably or best regulate the development of our real knowledge.

This conception of the necessity of mathematics was different from both Kant's and the logicists' and intuitionists'. So, too, was Hilbert's view of the cognitive richness of mathematics, which he attributed both to the objective richness of the shapes and combinatorial features of concrete signs and to the richness of our imaginations in 'creating' complementary ideal objects.

In its overall structure, Hilbert's mathematical epistemology thus resembled Kant's *general* critical epistemology. This included his so-called 'consistency' requirement (that is, the requirement that ideal reasoning not prove anything contrary to that which may be established by real means), which resembled Kant's demand that the faculty of reason not produce any judgment of the understanding that could not in principle be obtained solely from the understanding (1781/1787: A328/B385).

5 Modifications

During the first four decades of the twentieth century, each of the post-Kantian programmes outlined above came under attack. Frege's logicism was challenged by Russell's paradox. Russell's logicism encountered difficulties concerning its use of certain existence axioms (namely his axioms of reducibility and infinity) which did not appear to be laws of *logic*. Both were challenged by Gödel's incompleteness theorems, as was Hilbert's formalist programme. Finally, the intuitionists were criticized both philosophically, where their idealism was called into question, and mathematically, where their ability to support a significant body of mathematics remained in doubt. Various modifications have been proposed.

Modifications of logicism. On the mathematical side, a chastened successor to logicism can perhaps be seen in the model-theoretic work of Abraham Robinson and his followers. They are interested in determining the mathematical content latent in purely 'logical' features of various mathematical structures or the extent to which genuinely mathematical problems concerning these structures can be solved by purely logical (that is, model-theoretic) means. They have been particularly successful in their treatment of various algebraic structures (see Macintyre 1977; Robinson 1979; Hodges 1993).

Philosophically, too, there have been attempts to renew logicism. It re-emerged in the 1930s and 1940s as the favoured philosophy of mathematics of the logical empiricists (see Carnap 1931; Hahn 1933). They did not, however, develop a logicism of their own in the way that Dedekind, Frege and Russell did, but, rather, simply appropriated the technical work of Russell and Whitehead (modulo the usual reservations concerning the axioms of infinity and reducibility) and attempted to embed it in an overall empiricist epistemology.

This empiricist turn was a novel development in the history of logicism and represented a serious departure from both the original logicism of Leibniz (§10) and the more recent logicism of Frege (and Dedekind). It was less at odds with Russell's logicism which saw mathematics and the empirical sciences as both making use of an essentially inductive method (the so-called 'regressive' method - see Russell 1906, 1907).

Like all empiricists, the logical empiricists struggled with the Kantian problem of how to account for the apparent necessity of mathematics while at the same time being able to explain its cognitive richness. Their strategy was to empty mathematics of all non-analytic content while, at the same time, arguing that analytic truth and inference can be substantial and non-self-evident.

Their ideas came under heavy attack by W.V. Quine, who challenged their pivotal distinction between analytic and synthetic truths (1951, 1954). He argued that the basic unit of knowledge - the basic item of our thought that is tested against experience - is science as a whole and that this depends upon empirical evidence for its justification. Mathematics and logic are used to relate empirical evidence to the rest of science and, so, are inextricably interwoven into the whole fabric of science. They are thus part of the total body of science that is tested against experience and there is no clean way of dividing between truths of meaning (analytic truths) and truths of fact (synthetic truths).

Within a relatively brief period of time, Quine's argument became a major influence in the philosophy of mathematics and the logicism of the logical empiricists was largely abandoned. Newer conceptions of logicism have, however, continued to appear from time to time. For example, Putnam (1967) addressed the difficult (for a logicist) question of existence claims, arguing that such statements are to be seen as asserting the possible (as opposed to the actual) existence of structures. They are therefore, at bottom, logical claims, and can be established by logical (or metalogical) means. Hodes (1984) takes a somewhat different approach, arguing that arithmetic claims can be translated into a second-order logic in which the second-order variables range over functions and concepts (as opposed to objects). In this way, commitment to sets and other specifically mathematical objects can be eliminated and, this done, arithmetic can be considered a part of logic.

Field (1980, 1984) also presents a kind of logicist view - namely, that mathematical knowledge is (at least largely) logical knowledge. Mathematical knowledge is defined as that knowledge which separates a person who knows a lot of mathematics from a person who knows only a little, and it is then argued that what separates these two kinds of knowers is mainly logical knowledge; that is, knowledge of what follows from what.

Modifications of Hilbert's programme. Hilbert's programme too has its latter-day adherents. For the most part, these have adopted one of two basic stances: that of extending the methods available for proving the consistency of classical ideal mathematics; or that of diminishing the scope and strength of classical ideal mathematics so that its consistency (or the consistency of important parts of it) can more nearly be proved by the kinds of elementary means that Hilbert originally envisaged.

Some in the first group (for example, Gentzen, Ackermann and Gödel) have argued that there are types of evidence that exceed finitary evidence in strength but which have the same basic epistemic virtues as it. Others (for example, Kreisel 1958; Feferman 1988; Sieg 1988) argue for a change in our conception of what a consistency proof ought to do. They maintain that its essential obligation is to realize an epistemic gain, and that finitary methods are not the only epistemically gainful methods for proving consistency.

Those in the second group - the so-called 'reverse mathematics' school of Friedman, Simpson and others - try to isolate the mathematical 'cores' of the various areas of classical mathematics and prove the consistency of these 'reduced' theories by finitary or related means. So far, significant success has been achieved along these lines. (See Hilbert's programme and formalism §4.)

Modifications of intuitionism. Regarding intuitionism, Heyting's work in the 1930s to formalize intuitionism and

to identify its logic has led to a vigorous programme of logical and mathematical investigation (see Heyting 1956; Troelstra 1973, 1977; Beeson 1985 for descriptions of some of this work). In addition to Heyting and his students, Errett Bishop and his followers have extended a constructivist approach to areas of classical mathematics to which such an approach had previously not been extended (see Bridges 1987 for a survey).

On the more philosophical side, the most important development is the construction by Michael Dummett and his anti-realist followers of a defence of intuitionism based upon - in their view - the best answer to the question ‘What is the logic of mathematics?’. Their answer is based upon what they take to be a proper theory of meaning - a theory which, following certain ideas set out by Wittgenstein in his *Philosophical Investigations*, equates the meaning of an expression with its canonical use in the practice to which it belongs. They then identify the canonical use of an expression in mathematics with the role it plays in the central activity of proof, and from this they infer an intuitionist treatment of the logical operators (Dummett 1973, 1977).

6 Later developments

Along with the modifications of the major post-Kantian viewpoints noted above, two other developments in the second half of the twentieth century are important to note. One of these is the shift towards empiricism that was brought about by Quine’s (following Duhem’s) merging of mathematics and the empirical sciences into a single justificatory unit governed by a basically inductive-empirical method. On this view, mathematics may on the whole be *less* susceptible to falsification by sensory evidence than is natural science, but this is a difference of degree, not kind.

This conception of mathematics dispenses with a ‘datum’ of mathematical epistemology that philosophers of mathematics from Kant on down had struggled to accommodate: namely, the presumed necessity of mathematics. It puts in its place a general empiricist epistemology in which all judgments - those of mathematics and logic as well as those of the natural sciences - are seen as evidentially connected to sensory phenomena and, so, subject to empirical revision.

To accommodate the lingering conviction that mathematics is independent of empirical evidence in a way that natural science is not, Quine introduced a pragmatic distinction between them. Rational belief-revision, he said, is governed by a pragmatic concern to maximize the overall predictive and explanatory power of one’s total system of beliefs. Furthermore, predictive and explanatory power are generally aided by policies of revision which minimize, both in scope and severity, the changes that are made to a previously successful belief-system in response to recalcitrant experience.

Because of this, beliefs of mathematics and logic are typically less subject to empirical revision than beliefs of natural science and common sense since revising them generally (albeit, in Quine’s view, not inevitably) does more damage to a belief-system than does revising its common sense and natural scientific beliefs. The necessity of mathematics is thus accommodated in Quine’s epistemology by moving mathematics closer to the centre of a ‘web’ of human beliefs where beliefs are less susceptible to empirical revision than are the beliefs of natural science and common sense that lie closer to the edge of the web.

In Quine’s view, merging mathematics and science into a single belief-system also induces a realist conception of mathematics. Mathematical sentences must be treated as true in order to play their role in this system, and the world is to be seen as being populated by those entities that are among the values of the variables of true sentences. Mathematical entities are thus real because mathematical sentences play an integral part in our best total theory of experience (see Quine 1948, 1951; Putnam 1971, 1975).

Quine’s views have been challenged on various grounds. For example, Parsons (1980) argues that treating the elementary arithmetical parts of mathematics as being on an epistemological par with the hypotheses of theoretical physics fails to capture an epistemologically important distinction between the different kinds of evidentness displayed by the two. Even highly confirmed physical hypotheses such as ‘The earth moves around the sun’ are more ‘derivative’ (that is, roughly, more theory-laden) than is an elementary arithmetic proposition such as ‘ $7 + 5 = 12$’. It is therefore not plausible to regard the two claims as based on essentially the same type of evidence.

Others have challenged different aspects of Quine’s position. Field (1980) and Maddy (1980), for example, both

question his merging of mathematics and natural science, though in different ways. Field argues that natural science that utilizes mathematics is a conservative extension of it and, so, has no need of its entities. The mathematical part of natural science can thus, in an important sense, be separated from the rest of it. (See Shapiro (1983) for an apt criticism of Field's arguments.). Maddy investigates the possibility that our knowledge of at least certain mathematical objects might not be so diffuse and inextricable from the whole scheme of our natural scientific knowledge as Quine suggests. She argues that perceptual experience can be tied closely and specifically to certain mathematical objects (in particular, to certain sets) in a way that seems out of keeping with Quine's holism.

In addition to Quine, others have suggested different mergings of mathematics and natural sciences. Kitcher (1983), for instance, presents a generally empiricist epistemology for mathematics in which history and community are important epistemological forces. Gödel, on the other hand, argued that mathematics, like the natural sciences, makes use of what is essentially inductive justification ([1947] 1964: 477, 485) when it justifies higher-level mathematical hypotheses on the grounds of their explanatory or simplificatory effects on lower-level mathematical truths and on physics. He allowed, however, that only *some* of our mathematical knowledge arises from empirical sources and regarded as absurd the idea that all of it might do (1951: 311-12).

Another important influence on recent philosophy of mathematics is Benacerraf's 'Mathematical Truth' (1973), in which he argues that the philosophy of mathematics faces a general dilemma. It must give an account of both mathematical truth and mathematical knowledge. The former seems to demand abstract objects as the referents of singular terms in mathematical discourse. The latter, on the other hand, seems to demand that we avoid such referents. There are mathematical epistemologies (for example, various Platonist ones) that allow for a plausible account of the truth of mathematical sentences. Likewise, there are those (for example, various formalist ones) that allow for a plausible account of how we might come to *know* mathematical sentences. However, no known epistemology does both. Towards the end of the twentieth century a great deal of work has been devoted to resolving this dilemma. Field (1980, 1984), Hellman (1989) and Chihara (1990) attempt anti-Platonist resolutions. Maddy (1990), on the other hand, attempts a resolution at once Platonist and naturalistic. To date there is no general consensus on which approaches are the more plausible.

An earlier argument of Benacerraf's (see Benacerraf 1965, but also Dedekind 1888: §73; Hilbert 1900; Weyl 1927; Bernays 1950) was similarly influential in shaping later work. It is the chief inspiration of the position known as 'structuralism' - the view that mathematical objects are essentially positions in structures and have no important additional internal composition or nature (see Resnik 1981, 1982; Shapiro 1983). Apart from the desire for a descriptively more adequate account of mathematics, the chief motivation of structuralism is epistemological. Knowledge of the characteristics of individual abstract objects would seem to require naturalistically inexplicable powers of cognition. Knowledge of at least some structures, on the other hand, would appear to be explicable as the result of applying such classically empiricist means of cognition as abstraction to observable physical complexes. Structures identified via abstraction become part of the general framework of our thinking and can be extended and generalized in a variety of ways as the search for the simplest and most effective overall conceptual scheme is pursued.

Structuralism as a general philosophy of mathematics has been criticized by Parsons (1990) who argues that there are important mathematical objects for which structuralism is not an adequate account. These are the 'quasi-concrete' objects of mathematics - objects that are directly 'instantiated' or 'represented' by concrete objects (for example, geometric figures and symbols such as the so-called 'stroke numerals' of Hilbert's finitary arithmetic, where these are construed as types whose instances are written marks or symbols or uttered sounds). Such objects cannot be treated in a purely structuralist way because their 'representational' function cannot be reduced to the purely intrastructural relationships they bear to other objects within a given system. At the same time, however, they are among the most elementary and important mathematical entities there are.

Anscombe, Oxford: Blackwell, and Cambridge, MA: Harvard University Press, 2nd edn, 1967, part 1, appendix 2, 54-63; 3rd edn, 1978.(Presents statements of the later Wittgenstein’s view that a proof of a mathematical theorem functions to logically exclude doubt through its establishment of a theorem as a norm governing a language game.)

Matter

Viewed as arising within the framework of a more general theory of substance, *philosophical treatments of matter have traditionally revolved around two issues: (1) The nature of matter: what are the distinguishing characteristics of matter or material substance(s) that define it and distinguish it from other substances, if any? (2) The problem of elements: do material things consist of elementary substances, or are there always further constituents? One possible view is that there is no fundamental level - that there are always further constituents, ingredients of ingredients. However, the view most often held by both philosophers and scientists has been that there are indeed fundamental* elements *out of which material things are made. Once this view is adopted, the question arises as to what they are and what properties distinguish them.*

These two issues were introduced, though only gradually, in ancient Greek philosophy. A significant turn came about in the seventeenth century, in which the work of Descartes and Newton led to a picture of matter as passive, inert and dead as opposed to minds and forces, both of which were conceived as being 'active'. Many philosophical problems and doctrines have been formulated in terms of this distinction. However, later developments in science, especially in the twentieth century, have brought about such profound changes that classical concepts of matter are no longer viable. These new developments profoundly alter the statements of philosophical doctrines and problems traditionally associated with matter.

1 Ancient and medieval conceptions of matter

In Aristotle's view, matter is not a substance or an element. His own term for matter was reserved for one aspect of individual substances - particular objects like Socrates - which he saw as having both 'matter' and 'form'. Matter has the potential to receive form; it is never found in the absence of form, being inseparable from it. Thus Aristotle's matter is a bare *capacity* to have properties; it itself does not have any. This is in contrast to the matter of the seventeenth-century philosophers and scientists, which did have essential properties. Thus, 'the problem of matter' as usually conceived in modern philosophy stems from the concept of substance, specifically from the version of that concept which asserts that there are elements. From the perspective of this later view, the problem of matter in Aristotle is the problem of whether individual substances have 'constituents of which they are made' - the problem of elements - and not the problem of the nature of the 'potential to receive form' (see Aristotle §§13-14).

Aristotle attributed to his pre-Socratic predecessors the problem of the ultimate elements of which all things (material substances) consist. He thus saw the Milesian philosophers as maintaining that there is one material substance out of which all things are made - water for Thales, 'the Indefinite' for Anaximander, air for Anaximenes. Aristotle's interpretation of pre-Socratic philosophy is, however, questionable. According to some scholars, the Milesians (at least) were interested in the stuff *from which* things emerge, as things in nature grow from seeds or human beings 'come from' their parents, rather than, as Aristotle saw them, searching for the elementary constituents *of which* things are made. The shift of attention to the problem of elements was likely a gradual one, reaching relative maturity only with Empedocles, the atomists and Aristotle.

In Aristotle's interpretation, the Milesians were *monists*, believing that there is one material substance out of which all things are made. Monism was rejected following Parmenides, who maintained that if there is only one fundamental substance, change is impossible - a consequence his successors could not swallow. Parmenides argued that 'what is', or being, cannot have come into being, cannot change, cannot pass out of existence, is absolutely full (continuous, homogeneous, and as densely packed as possible), and is therefore 'one'. For example, it could only be separated by either nonbeing or being; but since nonbeing is nothing, it cannot separate anything; therefore between any parts of being there can only be more of the same, being. Similarly, if being changed, it could change only into being, that is, itself, since nonbeing is nothing. In order to account for the existence of change, post-Parmenidean philosophers turned to *pluralism*, the doctrine that there is more than one fundamental stuff (see Reduction, problems of). The atomists, Leucippus and Democritus, are clearest on this point. They admitted that ultimate reality must have most of the characteristics attributed to it by Parmenides, changelessness and permanence in particular. But in order to admit the existence of change and motion, they argued that there are many ultimate Parmenidean realities - the atoms - and, further, that nonbeing has some minimal kind of existence.

They identified nonbeing with empty space, through which the intrinsically unchangeable atoms could move and congregate to form the entities of our world (see Atomism, ancient). Other pluralist philosophers responded to the Parmenidean arguments similarly, declaring ultimate reality to be intrinsically unchangeable, the objects of familiar experience not having ultimate existence. Empedocles held that the four elements of earth, air, fire and water, which alone were truly fundamental realities (neglecting for present purposes the agencies love and strife), had the Parmenidean character of being uncreated and indestructible. The entities we know correspond to Parmenidean nonbeing, formed by the intermingling of the four elements through their motions. Anaxagoras said that there are an infinite number of 'seeds', each of which contains a little of everything (flesh, gold, …); larger bodies are formed when one of the infinite components of the seeds becomes dominant.

Plato, in the *Timaeus*, equated his equivalent of matter, the receptacle, with nonbeing, and also referred to it as space. Only the changeless forms truly exist, copies of them being embodied in the receptacle, which, like Aristotle's potentiality, is a mere capacity to receive form. As to the elements, the *Timaeus* presented a geometrical version of atomism in which the four elements, together with the universe, were identified with the five regular solids (see Plato §16).

Aristotle adopted a version of Empedocles' four-element theory, but with three major changes. First, the elements, like other substances, have both matter, in the sense of potentiality, and form, specifically two of the fundamental forms which together constitute the essence of the particular element. Thus the element earth has the fundamental forms 'cold' and 'dry', water 'cold' and 'wet', air 'cold' and 'dry', and fire 'hot' and 'dry'. (Indeed, for Aristotle, each type of entity has a distinct 'essential form' which constitutes its essence, making it the kind of substance it is. Except for the interconvertible elements, different types or species are irreducibly distinct: there simply are different species.) Second, the elements are interconvertible (they were not for Empedocles) by change of form: one fundamental form can 'drive out' its opposite. For example, 'dry' can drive out and replace the 'wet' in water, converting water into air. Third, Aristotle connected the four-element theory with his view of the structure of the universe: the 'natural place' of the element earth is in the central core of the universe, that of water in a spherical layer above earth, of air and fire in layers successively above that.

The Stoics also adopted a version of the four-element theory, but emphasized a distinction, present in Aristotle but not generally emphasized by him, between *passive* and *active* elements. Earth and water are passive elements, unable to move or otherwise act unless acted upon. Air and fire are active elements, capable of self-motion. The analogies between life and the active elements were not missed by the Stoics; indeed, a mixture of the active elements, *pneuma*, was the principle of life and intelligence, and constituted the 'soul of the world' which held the universe together as a unified *cosmos*. Although the Stoics saw the active elements as otherwise on a par with the passive ones in being material, their doctrine presages the Cartesian-Leibnizian distinction of mind and matter (see Stoicism §3).

Aristotle rejected atomism on several grounds, including its dismissal of final causes in nature. Despite a revival of atomism by Lucretius, Aristotle's rejection of the doctrine persisted among his medieval followers. However, atomism was not completely absent in medieval philosophy, being explored particularly among Islamic thinkers who followed the discipline *kalam*. Early *kalam* thinkers developed an atomistic conception of the universe as being freely created by God, but their attempt to affirm God's omnipotence as a causal agent based on his ability to create and sustain matter were refuted by Islamic Aristotelians and later by Al-Ghazali (see Causality and necessity in Islamic thought §3; Islamic theology).

The alchemists were responsible for most of the theoretical and experimental study of matter in the Middle Ages. Although their views were obscure, some were at least consistent with an Aristotelian viewpoint, seeing the purpose of alchemy as bringing the potential of matter to its fulfilment in the perfection of the higher metals and gems. Indeed, some of the alchemists seem to have believed that the formation of metals and gems in the earth was a natural process of growth and maturation, and that, through arcane knowledge, this process could be reproduced in the microcosmic laboratory. Thus they show the persistence of the ancient idea that things 'grow' in and from the ground (see Alchemy).

2 Matter in early modern science and philosophy

According to the conception of matter introduced in the Scientific Revolution of the seventeenth century, it is not

the case that there are many distinct types of material substance, each with its own essential and irreducible nature; rather, there is only one universal type of matter, with universal essential properties or ‘attributes’. All material bodies (and, for some, all entities whatever) are to be understood in terms of the motion of this fundamental matter. According to this view, introduced or at least popularized by Descartes and followed by Newton, matter is a *passive substance*, incapable of inducing its own action. All action of matter must be caused by an external agent. For Descartes, this external agent must be a *contact force*, and specifically an impact (collision); bodies will not move unless impacted (see Descartes, R. §11). In addition to impact forces, Isaac Newton allowed forces acting at a distance to affect matter. For Newton, matter consists of ultimate particles, atoms, which are discrete, localized, inert, ‘solid, massy, hard, impenetrable, movable’ and extended. (Note that the concept of inertness has shifted since Aristotle: whereas for him a body is inert if and only if it is at rest, for Descartes and Newton both rest and uniform rectilinear motion count as ‘inertial’, changeable only by the action of an external agent.) Passivity, inertness, deadness were now among the defining characteristics of material substance in addition to spatial extendedness, mobility and (Descartes excepted) impenetrability. Descartes distinguished such material substance sharply from *mind*, or *mental substance*, the latter being nonspatial and capable of initiating its own activity.

The basic difference between Descartes and Newton regarding matter was that Descartes conceived matter to be continuous and identified it with space, whereas Newton saw atoms as contingent occupants of space and consisting of physically (rather than logically) indivisible atoms occupying only a small proportion of the total space available in the universe. (In many places where he talks about the actual evolution of the universe and about particular physical problems, however, Descartes writes as though matter is a space-filling plenum rather than being identical with space.) Nevertheless, they agreed that it is of the nature of matter to persist in its inertial state of rest or uniform motion unless acted upon by an external force: that it is inert, dead, passive, blindly continuing in its present state, acting only when acted upon. Although Newton sometimes admitted action-at-a-distance (he also sometimes did not), he saw the power of attracting other bodies from a distance as contingently superimposed by God on matter, not part of the essential nature of matter, which was only passive. For most seventeenth-century thinkers, whether atomists or plenists, the basis of action in the universe was the impenetrability or hardness of matter, and action always took place by contact (see Mechanics, classical §4).

Leibniz criticized the Cartesian-Newtonian concept of matter on several grounds. He argued that the merely passive, whether space, time or matter, whether atomistic, plenum, purely space, cannot account for the unity of things, their individuation, change, resistance or impenetrability, or action. For example, the purely passive is incapable of explaining how one thing can affect another. Nor, since impenetrability is itself an activity of resistance, can the notion of a passive matter explain how objects can be affected by other objects. True substances - true fundamental realities - must be capable of action. Space, time and matter, being incapable of action, can only be ‘well-founded phenomena’, epiphenomena of non-material Active Forces or monads, which in their activity are more analogous to minds, capable of initiating their own activity, than to dead matter (see Leibniz, G.W. §11).

The issues raised by the ancient Greeks concerning the nature of matter and change are still present in these disputes between Leibniz and his opponents. The Parmenidean view of ultimate reality as necessarily unchanging is echoed in early modern theories of matter: where matter, whether atomistic or a continuous and space-filling plenum, was conceived of as permanent, indestructible and incapable of action. This view was challenged by the doctrine that the fundamentally real is capable of activity, a view with roots in Anaximenes and Heraclitus, later maintained by the Stoics, and carried by Leibniz to the extreme of asserting that only the active could exist.

3 Modern scientific views of matter and their philosophical relevance

In so far as the problem of matter is concerned with that of elementary constituents, an important development came in the history of chemistry. An empirically applicable concept of ‘element’ was utilized by Lavoisier: a material was to be treated as an element if: (a) with any of the means available to us, we cannot break it down into further constituents, (b) through such experiments, we always find members of the same class of substances as constituents, and (c) we find that other substances can be reconstructed by combinations of one or more of these ultimate breakdown products. Subsequent important steps in the history of chemistry revealed further evidence that there are a small number of such elements and that each element is fundamentally atomic. In the nineteenth century and culminating in the quantum-mechanical theory of the chemical bond, these developments led to a detailed theory of how atoms hold together in molecules and larger configurations (see Chemistry, philosophical

aspects of §4). However, it is now understood that the means which Lavoisier and his nineteenth-century successors used to break down substances (for example, heat and electricity) are low-energy processes, to be distinguished as ‘chemical’ from the forces that hold atomic nuclei themselves together (‘nuclear’ forces). Thus chemical atoms are now understood to be composed of more fundamental particles, electrons, protons and neutrons, the latter two consisting of still more basic particles, quarks. Although there remain dissenters, the view of most present-day particle physicists is that quarks and leptons (a category which includes electrons) are truly fundamental, without further constituents.

Modern scientific studies of matter have introduced further departures from the Cartesian-Newtonian ‘classical’ conception which are of profound relevance to philosophical discussions. While the concept of the indestructibility and conservation of mass is central to classical theories of mechanics and chemistry, relativity theories recognize that mass varies with frame of reference, and with velocity as measured in that reference-frame, and, further, that mass is interconvertible with energy (see Relativity theory, philosophical significance of). While Newton sharply distinguished forces from matter, in quantum mechanics forces are conveyed by transfer of a certain type of particles (the bosons) which has mass, like classical matter-particles. A second class of quantum-mechanical particles (‘fermions’) are intuitively closer analogues of classical matter in exhibiting impenetrability, but the correspondence is only rough. For example, fermions can also be exchanged in interactions, and they also exhibit wavelike (nonlocalized) behaviour. This latter feature is a consequence of deep features of quantum mechanics associated with the Heisenberg indeterminacy principles (see Quantum mechanics, interpretations of). For example, while in classical mechanics a knowledge of the simultaneous precise positions and momenta of the particles in an isolated system allowed prediction of the state of that system at any other time, in quantum mechanics it is impossible to assign simultaneous precise positions and momenta to particles. While the vacuum, or empty space, of classical physics was truly empty ‘nothingness’, particles appear and disappear spontaneously (causelessly, in any classical sense) from the dynamic vacua of modern quantum field theories (see Field theory, quantum §2). Those fields, while explanatory of immense bodies of scientific knowledge, are not classical entities with specific values of each of their assigned properties; the laws describing them are fundamentally probabilistic, treating them as superpositions of all quantum possibilities. Matter as conceived in modern physics is, in short, far different, and far more dynamic, than matter as conceived by Descartes and Newton. Finally, strong evidence indicates that there is far more matter in the universe than is detectable, at least by present instruments. Indeed, some observations and reasoning suggest that as much as 99 per cent of the matter in the universe may be of a kind different from the ordinary (‘baryonic’) matter we know (see Cosmology §3).

Thus the concept of matter has been altered in such drastic ways that certain contemporary ideas correspond at best only roughly to classical scientific and philosophical counterparts. The sharp contrasts between inert, passive permanence and dynamic activity, ultimate constituency and change, matter and force, fail to appear in quantum-theoretical analogues of classical matter. Indeed, the merely approximate analogy of fermions and bosons to classical concepts of matter, the activity of the quantum vacuum, the character of quantum fields as superpositions of possibilities and many other features of the quantum world, together with the existence of dark matter, all conspire to dictate the reformulation of many traditional problems of philosophy, such as the free will problem, the doctrines of materialism and determinism, the distinction between actuality and possibility, and the topic of matter itself.

Matter, Indian conceptions of

During the long and complex history of Indian philosophy, a number of divergent conceptions of matter have been developed and explored. These conceptions diverge both with respect to the ontological analysis of matter, and with respect to its specific structural characteristics. In terms of ontological conceptions of matter, the rival positions of materialism, idealism and substance-pluralism are all advanced by competing schools of thought. For example, pure materialism is espoused by the Cārvāka school, while absolute idealism is defended by Advaita Vedānta, and varying forms of pluralism are advocated by the Sāōkhya, Yoga, Nyāya and Vaiśeṣika schools.

Regarding the structural characteristics of matter, the most interesting conceptions are advanced by the pluralistic philosophies. In particular, the Vaiśeṣika and Nyāya schools recognize five physical substances, four of which are held to possess atomic structure. According to this conception, matter is composed of imperceptibly small units or paramāṇus*, which constitute the basic substrate in which perceptible qualities inhere. All macroscopic objects are transient composites of atoms, while the* paramāṇus *themselves are indivisible and indestructible. The atoms are held to be naturally at rest, and an external force is required to initiate motion.*

In contrast, the Sāōkhya and Yoga traditions espouse a metaphysical dualism of the two basic categories of matter and consciousness, where the continuity and dynamic transformations of matter are emphasized. All of the diverse phenomena of the physical world result from modifications of a single underlying source known as pradhāna *or primal matter, which is said to be continuous, all pervading, indestructible and imperceptible.* Pradhāna *exists in a balanced and unmanifest state of* pralaya *until it is disturbed by the presence of consciousness. This disturbance leads to an imbalance between the internal constituents of* pradhāna*, and the resulting disequilibrium accounts for the evolutionary transformations of the physical world.*

1 General survey

In the present context it is not possible to provide a comprehensive survey of Indian conceptions of matter, which have developed over several millennia among a number of divergent philosophical schools. Thus the current section sketches some of the most prominent features of the intellectual landscape, and §§2-3 focus in more detail upon two particular theories concerning the structural characteristics of matter, selected on the basis of their conceptual importance and interest.

The metaphysical position of materialism is represented in Indian thought by the heterodox Cārvāka school, which upholds an ontology in which only the physical elements possess ultimate reality, and everything that exists is a composite of these elements formed through the operation of strictly natural processes. In common with ancient Greek theories, the Cārvāka school adopts the four elements of earth, water, fire and air - in distinction to most other schools of Indian philosophy, which accept *ākāśa* or ‘ether’ as a fifth material element. According to the Cārvākas, since only the material elements are real, matter is responsible for thought, and it is the material body which gives rise to consciousness. Therefore, dissolution of the body at death entails the cessation of associated mental activity (see Materialism, Indian school of §4).

At the opposite end of the ontological spectrum, the idealist position that matter is ultimately ‘unreal’ was also advocated, most notably by the Advaita Vedānta school of Śaōkara. According to this view, absolute consciousness (*cit*) is the fundamental reality, and all particular manifestations, including the material world, are at root illusory. *Māyā* is the principle which sustains the appearance of all relative phenomena, and thus matter is ultimately diagnosed as *māyā*, an illusory appearance entertained by consciousness.

However, while the positions of pure materialism and absolute idealism are both represented in the history of Indian thought, some form of metaphysical pluralism is embraced by the majority of schools. Amongst these, matter is conceived as ontologically independent of mind (and vice versa), and this conception naturally motivates a rigorous investigation of the structure of the independent material realm. The atomistic pluralism of the Nyāya and Vaiśeṣika schools will be examined in §2, and the dualism of Sāōkhya-Yoga philosophy will be covered in §3. The heterodox Jaina tradition also embraced a form of atomism in many ways comparable to the Nyāya-Vaiśeṣika theory (see Jaina philosophy §1).

The extended intellectual conflict between the Hindu and Buddhist camps served to stimulate the development and

articulation of their respective positions, and the Hindu views discussed below implicitly assume the presence of Buddhist theory as a competing system. At the heart of Buddhist thought lies a vision of the world as a shifting and transitory array of particles, which lacks any underlying substrate to serve as the common thread holding the moments of existence together. According to the doctrine of momentariness (*kṣaṇikavada*), the world is an evanescent flux which is not materially preserved from one moment to the next, but rather consists in a series of discrete 'instants' (*kṣaṇas*) of existence, followed by complete annihilation before the next instant begins. Material objects, which appear as unitary and enduring, are analysed as mere aggregates, and possess no reality beyond the sum of their elemental parts (*dhātus*). So material objects are conceived as ontologically fragmentary and temporally discontinuous; real existence at each moment is granted only to the basic elements. These elements form momentary compounds, which, when viewed over a series of such moments, give the appearance of integral and continuous objects, much as a series of discrete frames supplies an illusion of continuity in a motion picture (see Buddhism, Ābhidharmika schools of §3; Buddhist philosophy, Indian §5; Momentariness, Buddhist doctrine of).

2 Vaiśeṣika atomism

Kaṇāda, legendary author of the *Vaiśeṣikasūtra*, is regarded as the founder of the Vaiśeṣika school, one of the six *darśanas* of orthodox Hindu philosophy. The name derives from the term *viśeṣa*, meaning 'ultimate particular', and this indicates the distinctively metaphysical orientation of the school. The Nyāya *darśana* of Akṣapāda Gautama is distinguished by its preoccupation with logic and epistemology, and forms the sister school to Vaiśeṣika. The atomistic theory discussed in this section is part of the shared Nyāya-Vaiśeṣika position, although it is primarily the contribution of the latter school (see Nyāya-Vaiśeṣika).

In contrast to Buddhist philosophy, the Vaiśeṣika position is that all qualities must inhere in a substance; properties cannot exist without an underlying substrate (*āśraya*) to ground them. According to this pluralistic account, there are nine such substances: earth, water, fire, air, ether (*ākāśa*), time, space (*dis*), mind (*manas*) and spirit (*ātman*), of which the first five are considered material substances. Each substance forms the ground for a characteristic quality: earth has smell, water has taste, fire has colour, air has touch and ether supports sound. Each substance either has infinite dimension or else is atomic in structure, a structural distinction which cuts across the material/nonmaterial divide. Of the material substances, earth, water, fire and air are atomic, while ether is infinite; and of the nonphysical elements, mind is atomic, while time, space and *ātman* are infinite.

Thus Vaiśeṣika recognizes four kinds of material atom (*paramāṇu*). The various macroscopic objects of the natural world are analysed as composites formed from *paramāṇus* of these four kinds, where the qualities of all objects are due to the qualities of the atoms of which they are composed. *Paramāṇus* have a number of distinguishing characteristics: they are indivisible and without parts (that is, genuinely atomic), they are unalterable and eternal, they are imperceptible, and they in fact lack spatial extension altogether and are held to be infinitesimal. In this manner, all substances are fundamentally either infinite or infinitesimal in magnitude.

The different atoms of a particular substance are qualitatively indistinguishable, but are none the less distinct particulars (*viśeṣas*). And there is only a qualitative difference between the atoms of different substances. As stated above, each substance has its characteristic quality, but this quality is not manifested at the level of the single atom. Rather, two atoms must combine to form a dyad, and three dyads combine to form a triad, which is the smallest level at which qualities are manifest. A triad is said to be of the magnitude of a 'mote of dust in sunlight', and the experienced world of matter is built up from such triads.

In contrast to the doctrine of momentariness, atoms are held to be indestructible and hence must persist through time, as do the composite objects of which they form the parts. But the composite objects, though persistent over finite intervals, are themselves ultimately transient and will eventually decompose. Thus matter at the macroscopic level is unstable, and atoms in motion constantly combine, disperse and recombine in new patterns.

In addition to dissolution at the level of particular objects, there is also a cosmic cycle of dissolution, stasis and reactivation, which forms a recurrent theme in Indian philosophy. According to Vaiśeṣika thought, atoms are naturally passive, so the entire universe eventually runs down. During cosmic stasis (*pralaya*), atoms subsist at rest without producing any effects. Original movement is due to external impact or activation, so the material world is not a closed system. A new cycle of the universe is initiated when an outside and 'unseen' force (*adṛṣta*) supplies

the impetus.

The need to appeal to an external and latently purposive source of activation is an explanatory defect in a theory of matter, and the Vedānta thinker Śaōkara criticizes the Vaiśeṣika account in this regard. The infinitesimal status of atoms is also problematic, since it would seem to entail that no finite collection of atoms could possess spatial magnitude, yet a mere triad is said to have perceptible dimensions. Śaōkara also criticizes the view that the atoms have no parts, since this seems to imply that they cannot structurally combine; if they combine as wholes, then they must collapse into each other and remain infinitesimal, and if they combine in parts then they are not indivisible.

A number of important differences distinguish Kaṇāda's view from the ancient Greek atomistic theories of Democritus (§2) and Epicurus (see Epicureanism §3), indicating that the two conceptions are probably independent. The Greeks hold atoms to be spatially extended, while as mentioned above, Kaṇāda contends that they lack dimension and are hence comparable to points in mathematical space. Additionally, the Greeks hold atoms to differ only quantitatively and not qualitatively, so that qualitative differences reduce to quantitative ones (for example, the figure, size and weight of the different atoms). In contrast, Kaṇāda takes qualitative difference as fundamental, while quantitative differences are analysed as macro-level features. The Greeks also believe atoms to be naturally in motion, as opposed to the Vaiśeṣika account summarized above, in which atoms are naturally at rest. Finally, the Greek view would reduce mind to matter (as would the Cārvākas), but the Vaiśeṣikas take mind (*manas*) as an independent (but none the less atomic) substance (see Atomism, ancient).

3 Sāōkhya dualism

The Sāōkhya *darśana* is one of the oldest philosophical traditions of India, and many of its ideas are traceable to the *Ṛg Veda* and early Upaniṣads. Its historical founder is Kapila, though the original *Sāōkhyasūtra* he is said to have written during the sixth or seventh century BC is now lost, and the most important of the existing texts is the *Sāōkhyakārikā* of Īśvarakṛṣṇa, from around the third century AD. The Sāōkhya tradition has a great many points in common with the classical Yoga *darśana* expounded in Patañjali's *Yogasūtra*, and the conception of matter discussed in the present section is part of their shared philosophical framework (see Sāōkhya).

According to the Sāōkhya-Yoga view, the varied phenomena of the material world are all manifestations of a single underlying source. The metaphysical principle underpinning all physical manifestation is *pradhāna* or primal matter, which can be thought of as a form of pure potentiality, the ultimate base supporting all modifications and transformations. *Prakṛti* is another term used synonymously with *pradhāna* to denote the metaphysical basis of matter. As such, *prakṛti* is the unmanifest (*avyakta*) and uncaused origin of the physical universe. *Prakṛti* is said to be continuous, all-pervading and eternal. Although continuous, it is differentiated into three constituent powers or *guṇas*, and the interaction of the *guṇas* is responsible for the dynamics of manifestation and transformation. The three *guṇas* are *sattva*, *rajas* and *tamas*, which correspond roughly with 'transparency and form', 'energy and motion' and 'inertia and obstruction'. The *guṇas* are opposing and mutually unstable forces intrinsic to the nature of *prakṛti*, and they cannot be separated or merged. All three are present in all material phenomena, and the differences between diverse objects are ultimately traceable to the predominance or proportions of the different *guṇas*.

Prior to the phase of manifestation which results in matter, *prakṛti* exists in the equilibrium state of *pralaya*. This is not a passive state of rest as in Nyāya-Vaiśeṣika, but consists rather in the tension of opposing forces in perfect balance. When this balance is disturbed, the process of becoming is set in motion, and material manifestation is thus seen as a state of disequilibrium. Once out of balance, the 'mechanical' interplay of the *guṇas* results in the evolution of the universe; the destabilized triad of forces counterbalance and readjust in a shifting pattern of transmutation.

Pradhāna gives rise to the material elements, which are said to be atomic in structure. However, unlike the Nyāya-Vaiśeṣika theory, this atomism is a physical rather than a metaphysical thesis, since the atoms themselves are manifestations of a continuous substrate. Thus the atoms are not *metaphysically* discrete, and the five material elements still reduce to the three *guṇas*.

Material actuality emerges from the state of potentiality, and to that source it returns. There is no genuine creation or annihilation in the Sāōkhya view, but rather a sort of metaphysical unfolding and consequent reabsorption into

the realm of latent possibility. Like the Vaiśeṣika atoms, *pradhāna* itself is eternal and indestructible. Eventually the entire universe follows the same course as its individual members, and is reabsorbed into the state of potentiality; the equilibrium of *pralaya* is once again obtained, giving rise to the familiar cycle of cosmic emergence and dissolution.

Prakṛti is inherently unconscious, and is held to be incapable of producing consciousness as an effect; the evolution of matter is a 'blind' mechanical affair. According to the Sāōkhya-Yoga view, subjective awareness belongs to a different ontological category altogether, the realm of *puruṣa* or pure sentience. *Puruṣa* forms the other metaphysical pole in the dualistic system, and is said to consist of undifferentiated consciousness which is immutable and inactive, formless and without parts. However, in sharp contrast to Cartesian dualism, Sāōkhya theory holds that mental faculties and activities are at root material; the mind is a manifestation of *prakṛti* rather than *puruṣa*. Thought is characterized by form and motion, which are distinctive attributes of matter, while consciousness is formless and inactive. Hence the basic metaphysical schism between consciousness and matter then leads to an ancillary dualism between consciousness and mind.

Pure consciousness or *puruṣa* is passive and does not guide the evolution of matter, so it does not guide the progression of thought, which is a strictly material process. However, it is consciousness which triggers the disequilibrium leading from *pralaya* to manifestation. This is not an act of volition or agency on the part of *puruṣa*, but is said to be a mechanical force, like magnetic attraction, which results merely from the proximity of the two substances. So even though consciousness does not influence the specific development of matter, it supplies the initial disturbance that throws *prakṛti* into the disequilibrium of material processes.

Thus *puruṣa* plays a role similar to the Vaiśeṣika *adṛṣṭa* in triggering a cycle of material manifestation, though in the Vaiśeṣika account this is more a purposive or teleological event, while in Sāōkhya thought it is involuntary. Also, in the Sāōkhya picture, the energy which drives the evolution of matter does not derive from an external source, but rather is an expression of *prakṛti*'s inherent powers as they unconsciously unfold. But the Sāōkhya-Yoga picture is still clouded with respect to the precise nature of the interaction between the two substances. The fact that *prakṛti* can be 'mechanically' influenced indicates that it is not a closed system, and the fact that *puruṣa* can affect *prakṛti*, even unintentionally, indicates that consciousness is not purely inactive.

After *pralaya* has been disrupted and the cycle of manifestation has commenced, the two substances must continue their 'interaction' to produce the phenomenon of conscious mental activity. Thought processes and mental events are conscious only to the extent that they receive external 'illumination' from *puruṣa*, and it is the *sattva* constituent of matter which is able to 'absorb' this conscious radiance. The *sattva guṇa* is held to be 'transparent', while consciousness is often compared to a ray of light. The component of the mind known as *buddhi* or pure intellect (which is in some ways comparable to the Greek *nous*) is believed to consist of a preponderance of the transparent *sattva guṇa*, and this enables the material thought process of *buddhi* to become illuminated by the external light of consciousness. However, pure consciousness is held to be entirely independent of the mental structures it illuminates, just as sunlight does not *choose* to pass through particular transparent objects which happen to lie in its path.

The translucent quality of *buddhi* distinguishes thought-stuff from the grosser material objects of thought and perception, which ordinarily contain a preponderance of the 'dark' or opaque *tamas guṇa*. Thus only the thought material of *buddhi* is capable of conscious illumination, rather than the entire material realm, since a preponderance of the *tamas guṇa* renders the external objects of the material realm opaque to the light of consciousness. This is why minds appear to be conscious while stones and tables do not; only the subtle stuff of the *buddhi* is a suitable medium for receiving sentience, and thus it is minds which are the apparent loci of awareness in the material world.

Matthew of Aquasparta (*c.*1238-1302)

Matthew walked in the footsteps of Bonaventure, which were widened by his first followers, Walter of Bruges, John Pecham and William of Mare. For them, the knowledge of God's existence is the first truth implanted in the human mind. God's existence cannot be proved a priori (from something prior to it), since it is the first truth. It is a truth that is immediately known, not in the sense that there is actual knowledge of God implanted in the mind at birth, but because any judgment we make presupposes that the mind has contact with the Truth that is the measure of all truth. Such a first Truth must exist.

Born in the Italian village of Aquasparta, near Todi, Matthew came from the distinguished Bentivenghi family. A Franciscan friar, who often provided a response from the school of Bonaventure to the philosophy of Aquinas, he qualified as a *baccalareus biblicus* (lecturer on the Bible) at Paris in 1268 and *baccalareus Sententiarum* (lecturer on Lombard's *Sentences*) in 1273. He lectured at Bologna from 1273-7 and then became regent master at Paris from 1277-9, before being named lector at the Roman curia from 1279-87. He was elected General Minister of the Franciscans at Montpellier in 1287 and fulfilled this charge until 1289, even after being named a cardinal in 1288. He served the Holy See under Pope Boniface VIII until his death in 1302.

Following Anselm's path, Matthew argues: 'If the first and highest being is the first and highest being, it necessarily follows that the first and highest being exists, for what is first and highest is most actual and most perfect, and for this reason exists *in actu* (actually), since existence is of the very nature of a first and highest being. Indeed, existence is identical with such a being' (*Quaestiones disputatae de productione rerum et de providentia (Disputed Questions on the Production of Things and on Providence)* 11-12). Matthew, however, holds that it is also necessary to approach the question of God's existence from empirical grounds. Such an approach allows us to make more explicit the knowledge of God that is implied in any of our original judgments. He argues, first of all, from the imperfection and mutability of finite beings to the need for their perfect and immutable foundation, and then from the orderly way in which the world runs and the goals things naturally pursue, to a first efficient and final cause (*De productione rerum* 12-17).

As the first and highest being, God knows and loves in the highest degree. Infinitely fulfilled in his own perfection, 'the first being neither makes nor conserves anything unknowingly, nor irrationally, nor by chance, nor by the necessity of his nature, but knowingly and with foresight and in an orderly way' (*De productione rerum* 36). God, as first and highest being, does not need anything. If he created a universe, it could be only to share his supreme goodness. Out of this infinite goodness, Matthew argues, God created rational creatures capable of knowledge and love, and consequently capable of happiness, to manifest and share his boundless perfection (see Creation and conservation, religious doctrine of; God, concepts of).

In treating of creation, Matthew enters into the debate raging in the 1270s between the Averroists contending that the eternity of the world could be rationally demonstrated and the theologians who denied the validity of their proofs (see Averroism). Aquinas, admitting the temporal character of creation as an article of faith, contended that reason could demonstrate neither the temporal nor the eternal nature of creation. Matthew attacked Aquinas' efforts to show that specific arguments against the eternity of the world are not demonstrations. For Matthew, an eternal world would imply the existence of an infinite number of souls, or revolutions of the sun, or generations. These arguments against an eternal creation are necessary reasons, and the attempts of Aquinas to rebut them are sophistical (see Eternity of the world, medieval views of).

Matthew holds that the 'agent' and 'possible' intellects are cognitive faculties belonging to the soul itself. However, they need the assistance of divine illumination to arrive at perfect, evident and necessarily true cognition. In his commentary on Book I of the *Sentences* (d. 35, q. 8), following Guibert of Tournai, he portrays this illumination as a special created light given by God. In his later *Quaestiones disputatae de cognitione (Disputed Questions on Knowledge)*, returning to Bonaventure's position, he argues that this light must be God himself. Special assistance is required because the spiritual nature of the soul prevents it from being affected by sensible objects. The agent intellect, then, assisted by divine illumination, forms intelligible species of sense objects and impresses them on the possible intellect. Objects and the intellect are partial causes of knowledge, but the intellect is the principal cause. In regard to certain and necessary knowledge, however, the intellect is a

secondary efficient cause; the primary cause is the divine light. The soul has a direct knowledge of itself. Concepts of purely immaterial entities, such as God, angels, the good or first principles, are innate or impressed in the soul and are not abstracted from the outside world.

Matthew is very much influenced by Aristotle's philosophy, especially as elaborated by Aquinas. Even when he rejects Aquinas' positions, Matthew's arguments are not simply repetitions of those of Bonaventure and his early followers. They are serious attempts to overcome Aquinas' theses. For instance, when Aquinas holds that the will acts according to the directives it receives from reason or intellect, Matthew objects that, while needing enlightenment from the intellect, the will itself activates the intellect, giving it commands and stimulating it to action. The will is superior to the intellect, first because its perfection, charity, is superior to the intellect's perfection, faith; and secondly, because its object, goodness, is superior to the intellect's object, truth. Will, not reason, is also the centre of freedom. Reason is necessary to enable us to conceive the possible choices open to us, and to deliberate about them; but it is the will which produces free human action, since a person depends on will when deciding to accept or reject what reason proposes (see Free will).

Mauthner, Fritz (1849-1923)

The work of Fritz Mauthner helps document the phenomenon of 'language crisis' or Sprachkrise *in German-Austrian letters at the beginning of the twentieth century. In his Beiträge zu einer Kritik der Sprache (Contributions to a Critique of Language) (1901-2), Mauthner develops a theory of knowledge that draws on empiricism but also redefines certain basic concepts in terms of language. 'Language' refers to more than speech; it is the medium of all cognition and, as such, an instrument of knowledge. Mauthner's reformulation of epistemological questions in linguistic terms does more than replace one topic with another. When language becomes the focus of philosophical debate, the debate cannot help but involve a discussion of the nature and limits of the discussion itself. As epistemology or theory of knowledge gives way to critique of language, it spells the end of philosophy as a foundational discourse for the human sciences.*

1 Language in thought and communication

The philosophical tradition with which Mauthner aligns himself most consistently is that of empiricism (see Empiricism). He acknowledges debts to Kant, Locke and Hume, and sees his work as the continuation or even completion of their inquiries into the possibility of knowledge. Mauthner also stresses his divergence from these three philosophers with his notion of the 'contingent senses' or *Zufallssinne*. He outlines a traditional-sounding sceptical thesis about the limits and accuracy of empirical knowledge, then gives the argument an evolutionistic turn. He holds that the senses are contingent on human needs and have undergone modifications over time corresponding to shifts in those needs. Therefore sense data reflect what is useful, and utility by no means implies accuracy. On the contrary, Mauthner presents the filtering, organizing activity of the senses as a process of distortion.

Out of his scepticism about knowledge through the *Zufallssinne* grows his thesis that language provides only *Zufallsbilder* ('contingent images') of the world. The process of concept formation that begins with sense information also marks the first instance of language. 'Language' is the very medium in which mental pictures of reality are created. According to Mauthner, language is synonymous with reason, cognition and the work of memory. By proclaiming that there is no such thing as 'pure reason' (*reine Vernunft*) but only 'linguistic reason' (*sprachliche Vernunft*), Mauthner echoes a criticism of Kantian epistemology voiced already by Hamann and Herder in the eighteenth century. In this connection he also introduces the term 'metaphor'. By describing the relation between mind and world as metaphorical, Mauthner underlines his point about the linguistic character of all knowledge, since 'metaphor' is a literary trope and an element of rhetoric. The term also serves as a reminder that knowledge is limited: it results from the transformation or translation of sensations into concepts, and something is always lost in translation.

Mauthner's scepticism about an individual's ability to achieve true knowledge also bears directly on his view of language as a means of communication. The notion of a gap between the sensible and intelligible is already introduced with the thesis of the *Zufallssinne*, and the gap widens twice: first, when sense data become schematized in language (here understood in the psychological sense), and again when translated into the language shared by members of a linguistic community. Spoken or written language in Mauthner's view thus stands at a double remove from reality. He contends that because no two people have the same perceptions or thoughts, what they express by means of their communal language is virtually worthless. While admitting that the 'misrepresentations' are adequate for the demands of daily life, Mauthner does not conclude that any other form of knowledge is unnecessary or impossible. He retains instead the premise that knowledge consists in accurate representations of reality, and predictably arrives at sceptical conclusions about the ability of language to provide such knowledge.

2 Philosophy as critique of language

At the beginning of *Beiträge zu einer Kritik der Sprache (Contributions to a Critique of Language)* (1901-2), Mauthner admits that language must play a double role: it is the vehicle of the critique, and also the object of study. But the full extent of the problem becomes clear only when he has developed the thesis about the inadequacy of language as an instrument of knowledge. This argument raises the question of whether it is possible to claim the inadequacy of language without at least implicitly granting the claim itself a special authoritative

status. In other words, does Mauthner's critique itself reflect or bear out the claims about language that it makes? His scepticism would seem to point toward silence, yet Mauthner continues to write after finishing the *Kritik*. Mysticism, too, receives considerable attention in his work, and suggests another possible outcome of language critique. Silence and mysticism, however, remain potential answers rather than actual responses, options that Mauthner discusses but does not choose. The reason lies in the fact that language also has a social dimension which even Mauthner, for all his emphasis on the individual, psychological aspect of language, cannot overlook. When writing about language as a form of communication, he dismisses it as the language of the 'herd', which he feels has nothing to do with the object of his critique. What complicates the situation is that he, too, remains subject to the social force of language. In short, while Mauthner decries the tyranny of language on the first page of his *Kritik*, he still cannot escape it, and he admits as much in several different but related ways.

Naming the individual as the locus of (epistemological) value is itself a gesture that reflects social or communal agreement. The implied community in this case consists of philosophers writing before and at the same time as Mauthner, who likewise concentrate on the individual subject when theorizing about knowledge. In this context he also retains traditional metaphors of vision and representation, and thereby signals once more that he is participating in an ongoing conversation. Perhaps the clearest indication of how the social character of language in effect wins out over the individual-oriented aspect lies in Mauthner's statements about the purpose of his critique. He observes that unless others read his work and adopt his ideas, the critique has absolutely no value, and in his eyes is not even 'real'. He emphasizes his dependence on a community with another metaphor: calling language both a 'social game' (*Gesellschaftsspiel*) and 'the social game of knowing', he characterizes his own efforts as an attempt to change the rules.

On occasion Mauthner seems to grant his own work a voice of authority in traditional Kantian fashion, but other passages reveal that he questions philosophy's ability to provide knowledge or access to truth. He declares for instance that although individual philosophers and philosophies (plural) exist, there is no such entity as 'philosophy' (singular). In his view, philosophy-as-language-critique is indeed the discipline that investigates the working assumptions of other disciplines, but because the inquiry is not written in any sort of metalanguage, philosophy no longer occupies the foundational position it once held. As critique of language it has irrevocably lost its authoritative voice.

3 Reception and later works

Several of Mauthner's later works move away from the emphasis on individual psychology that characterizes his critique. *Die Sprache (Language)* (1906), for example, addresses questions about language as a social phenomenon including attempts to develop an international language or Esperanto, and different forms of translation. Mauthner draws attention to the shift in focus when he notes that the concept of a *sensorium commune* has been borrowed from 'older' psychology and applied to language in a social context, where in his view it becomes more tangible and accessible than when used in reference to the individual mind.

In *Die Sprache* Mauthner mentions an ambitious, now abandoned plan to write an 'international' historical dictionary that would document processes of translation. The somewhat more modest project that takes its place is his *Wörterbuch der Philosophie (Dictionary of Philosophy)* (1910-1), subtitled 'New Contributions to a Critique of Language'. Beyond tracing semantic change in some two hundred philosophical terms, Mauthner hopes to persuade his readers that meanings are anything but stable and that, because there are no fixed referents in language, there is no true knowledge. Because his nominalism skews the perspective decidedly, the dictionary is not always entirely reliable as a reference work. None the less, individual articles contain a wealth of historical information, and also provide condensed versions of arguments advanced in the *Kritik*.

The other major work that Mauthner published during his lifetime was a four-volume history of atheism. Although quite different in style from his philosophical dictionary, this work reflects the same basic argument that linguistic meaning is determined by use, and therefore changes over time. In his autobiographical writings Mauthner admits that at the time he began speculating about the existence of God, he probably did not recognize any link between his religious doubts and his growing interest in language. But as an adult, and more specifically as the author of a work on atheism, he perceives and even insists on the connection. He describes the history as the 'history of a word, the negative word-history of the gradual devaluation of the word "God"' (*Der Atheismus und seine Geschichte im Abendlande*, 1920-3). He intends to prove that belief in 'God' as anything more than a word is a

form of word superstition.

In addition to the dictionary and the work on atheism, Mauthner completed short monographs on Aristotle, Spinoza and Schopenhauer. He also wrote the first (and only) volume of his memoirs, and edited several volumes in the series *Bibliothek der Philosophen* (Library of Philosophers), which was discontinued at the beginning of the First World War. The volumes on which Mauthner worked were on Fritz Jacobi's *Spinozabüchlein*, Agrippa von Nettesheim and the nineteenth-century philosopher of language O.F. Gruppe.

During his lifetime Mauthner enjoyed wide recognition, albeit not as a philosopher. He worked as a professional journalist for over twenty years in Berlin and, prior to writing the *Kritik*, also published novels, novellas and essay volumes in addition to a popular collection of literary parodies. Mauthner's literary and journalistic writings led many academic philosophers to dismiss his language critique as the work of a dilettante, but his work was taken seriously by thinkers including Ernst Mach, Hans Vaihinger and Martin Buber. After his death, Mauthner's work came to attention only gradually, in part because his extreme scepticism was so incompatible with more dominant trends in philosophy such as phenomenology and logical positivism.

Mauthner has the dubious distinction of being mentioned by name in Ludwig Wittgenstein's *Tractatus Logico-Philosophicus* (1922: 4.31), where we read: 'All philosophy is a "critique of language". (Though not in Mauthner's sense.)'. Wittgenstein takes very different stances from Mauthner's on such issues as the possibility of scientific knowledge, and maintains that congruence actually does exist between reality and language (in the form of logical propositions). Despite this important basic difference, the *Tractatus* and Mauthner's *Kritik* both end with a turn toward mysticism. For Mauthner the premise that some unmediated and extralinguistic mode of experience exists leads to a mystical yearning for that kind of experience. Wittgenstein, after working through propositions about what is sayable, declares that some things still elude us, and that these things may ultimately be more important than any knowledge we do have.

How well Wittgenstein knew Mauthner's work is not clear, but there is general agreement that their affinities emerge more clearly if we look at Wittgenstein's later work, particularly *Philosophical Investigations* (1953), where the notions of language game and meaning as use recall Mauthner's positions. Wittgenstein's description of his project as a way of showing the fly the way out of the fly bottle also seems to echo Mauthner, who stresses the salutary effect of critique of language. His attacks on 'word fetishism' and his insistence on the impossibility of attaining knowledge earned him an early reputation as a nihilist, which he himself rejected. Critique of language unmasks and destroys idols in the name of liberation, he argues; it should not be feared as a threat but welcomed as a sorely needed form of philosophical therapy.

Maxwell, James Clerk (1831-79)

For his two achievements of unifying electricity, magnetism and light, and of inventing statistical dynamics, Maxwell stands as the founding mind of modern theoretical physics. More than any other physicist's his also was a mind shaped and informed by a training in philosophy, even though, unlike Heinrich Hertz or Ernst Mach, for example, he never wrote a philosophical treatise. Therein lies the point, however. Mach's and Hertz's best discoveries seem remote from their metaphysics, Maxwell's are bound up with his. Particularly important philosophically are his interconnected uses of relation, analogy and classification. He is also responsible for introducing the word 'relativity' into physics, and for articulating the scientific problematic that led to Einstein's theory.

1 Physics and metaphysics

Born in Edinburgh, Maxwell spent three years at Edinburgh University and learned philosophy there from Sir William Hamilton. Hamilton was a critical rather than systematic thinker, and was influenced by Kant. His greatest gift to Maxwell was a human one - contact with a searching and erudite mind. Most potent among specifics was his doctrine of the 'relativity' of human knowledge - a word he coined in opposition to the post-Kantian idealists Fichte, Schelling and Hegel. Contrasting knowledge with belief, Hamilton held that while we may believe in the absolute we know nothing absolutely. All knowledge involves relations, either our own to the object or of objects to each other.

Maxwell migrated to Cambridge in 1850. There he gained another, different Kantian guide, William Whewell. Whewell's focus was science. In 1830 his friend John Herschel had written a brilliant sketch of early nineteenth-century discovery framed to illustrate Baconian principles - the work from which John Stuart Mill borrowed the five methods of induction now called his (see Science, 19th century philosophy of §4). Whewell demurred, holding that while each science starts with Baconian observation, sooner or later it undergoes transition to a higher Kantian state governed by certain 'appropriate ideas' having an inner authority of their own, independent of the experiments that suggested them. Take Newton's inverse-square law of gravitation. Why is this exact? Kant had guessed a connection with the tridimensionality of space, since the surface area of a sphere in three dimensions is $4\pi r^2$. Whewell gave other examples, arguing that one mark of 'appropriateness' is simplicity, or, as modern physicists say, 'beauty'.

First an artist, then a poet, then a geometer, all before he was fifteen, Maxwell was that paradox, a slowly maturing prodigy. Of his first nine publications other than poems, five treated geometry, two colour vision, one - half-experimental - physics. Not until after his graduation from Cambridge did he join physics to ' metaphysics [in] the rigid high style…about ten times as far *above* Whewell as Mill is *below* him, or Comte or Macaulay *below* Mill, using above and below conventionally like up and down [trains] in Bradshaw['s railway timetable]' ([Letter to R.B. Litchfield 4 July 1856] Campbell and Garnett 1882: 261).

Maxwell's work is a barrage of classifications. Classification of dynamical quantities, of electrical ones, of transport processes, of colours, classification in thermodynamics, various mathematical classifications, classification by dimensional analysis, classifications of instruments, diagrams, experimental techniques, laboratory designs, modes of research, types of scientific paper, even (wittily) of scientific meetings - all occur. With this multiplicity, in but not limited to the classifications, are *dualities*: two ways of classifying dynamical topics, two of vectors, two of colours, two of physical quantities at large, a dual classification of electrical units, dualities in optics, thermodynamics, electromagnetism, two approaches to harmonic analysis, two to potential theory, a dual definition of electromotive force. In electromagnetism, these dualities and multiple classifications connect with Hamiltonian relativity, with Faraday's ideas, and with mathematical analogies by Maxwell's fellow Scot William Thomson (Lord Kelvin), as will now appear.

2 The electromagnetic field

Maxwell's theory united electricity, magnetism and light, it created radio, generated the relativity crisis, and set physics on a new path - field theory. Rich in discovery, new in form, startling in its picture of the electric current as an entity extending beyond the confines of the wire that guides it, this was more than a new theory. It was a

new*kind* of theory.

According to Maxwell, two magnets (or charges or electric currents) do not act on each other directly. Each separately stores up energy in the surrounding space (the 'field') and the forces arise indirectly via the field. A natural question is whether this indirect transmission is instantaneous. To his astonishment Maxwell found that electrical signals propagate through space as waves with a velocity identical with that of light. Moreover, these waves *had to be* transverse. The problem of the longitudinal wave, the nightmare of mechanical ethers, had evaporated (see Electrodynamics; Field theory, classical).

Earlier workers had sought causes; Maxwell sought relations. Instead of *explaining* light or electromagnetism he established a relation between the two, and the central structure of his theory is neither a law nor a set of axioms but a system of relations among electric and magnetic quantities - Maxwell's equations. These he grouped in two ways. One, *electrical*, comprised the four equations we now call his; the other, *dynamical*, included also the 'Lorentz' force and the vector potential A. Compactness plus a belief that A is unphysical made his successors prefer the first. Maxwell saw further. He wrote in 1873: ' Our object at present is not to obtain compactness in the mathematical formulae but to express every relation of which we have any knowledge. To eliminate a quantity that expresses a useful idea would be rather a loss than a gain at this stage of our enquiry' (Maxwell 1873, vol. II: 234).

Electric currents produce not attractions, but *circular* magnetic forces. Why? Earlier opinion had been divided. To Ampère and Wilhelm Weber the effect was secondary, reducible to underlying attractive-repulsive forces, albeit forces entangling strange additional dependencies on angles (Ampère) or relative motions (Weber). To Faraday, the instinctive geometer mapping lines of force, such explanations seemed perverse, a reduction of the simple to the complex, especially when he found that even electrostatic forces act in curved lines. And so to Maxwell's first paper (1856).

Picture - the analogy is Thomson's - a fixed elastic solid in which is embedded a long straight wire. Pull the wire a distance i′. The solid will become cylindrically distorted, with displacements A′ parallel to i′ and consequent twistings B′ about directions circling the wire. Different as they are physically, these quantities i′, B′, A′ correspond geometrically to current i, magnetic force B and Maxwell's A in electromagnetism. Transcending geometry, Maxwell then made a spectacular discovery. Other electromagnetic phenomena also depend neatly on A. Here was a theory, dual to Weber's, advantageous precisely because it did not ' even in appearance, *account for* anything' (Maxwell 1890, vol. I: 207)

A second analogy, between lines of force and fluid motion, enabled Maxwell to mesh Faraday's curved lines of force with classical potential theory, and legitimize Kant's argument about the inverse-square law. Inverse-square forces entail a field satisfying a continuity equation. The law rests on experiment but any departure from it means large changes in theory - a different underlying geometry, say, as with gravity in Einstein's theory, or radically different field concepts as with nuclear forces.

Different equations, Maxwell's and Weber's, cover the same phenomena. Different phenomena, electric force and fluid motion, obey the same equations. Such dualities, with analogy, subvert conventional scientific explanation. Even more peculiar is the union, geometrical not physical, between Coulomb's and Faraday's theories, effected by an analogy unrelated physically to either. It is puzzles like these that destroy the well-known saying by Heinrich Hertz, that ' Maxwell's theory is Maxwell's system of equations', and analogies merely 'gay garments' clothing 'the simple and homely figure' of nature (Hertz 1893: 21, 28). How strangely have Hertz's admirers failed to see his couturierial vision as itself an analogy, and a singularly inept one. For Maxwell's problem is just this - how to link fact, concept, and equation when each holds multiple meanings.

One duality that Maxwell, with magian prescience, illumined was between wave and particle theories of light. ' That theories so fundamentally opposed should have so large a field of truth common to both is a fact the philosophical importance of which we cannot fully appreciate until we have reached a scientific altitude from which the true relation between hypotheses so very different can be seen' (Maxwell 1890, vol. II: 228).

Was all theory analogy? Maxwell's in its dynamical form illustrates the complexities. It was in two senses hybrid. It inserted electrical energies into dynamical equations, and it contained some things literal, others analogical. Field energy was - energy. *Electrokinetic momentum*, Maxwell's new name for his old A, was an analogy.

That A resembles *momentum* for currents and *potential* for forces shows the subtlety of 'scientific metaphor'. Long neglected, the momentum analogy gained new life with quantum mechanics. In 1959, Y. Aharonov and D. Bohm proved, against eighty years of post-Maxwellian wisdom, that through it, A has direct physical meaning.

3 Gases, molecules, statistics

Maxwell did not introduce statistics into physics, or invent gas theory, or first fix molecular sizes. Yet he revolutionized all three, pondered metaphysical consequences and, long before Planck, quanta, and the 'ultraviolet catastrophe', saw here alongside triumph sudden scientific disaster.

It was Clausius who brought in statistics. Recognizing that the fast-moving molecules of gases must constantly collide, he defined in 1858 a characteristic mean *distance* between collisions, taking all molecules to have the same speed. Correcting this, Maxwell treated *speed* also statistically by computing a 'velocity distribution function'. Then came classification. Linking three disjoint phenomena, diffusion, viscosity, thermal conduction, to transport through the gas, respectively, of mass, momentum, and energy, he obtained, among much else, two separate, very good estimates of the free path in air ($\sim 6 \times 10^{-6}\,\mathrm{cm}$), and the astonishing result that viscosity is over a wide range independent of pressure. Investigations of extreme technical sophistication followed, not least the great paper of 1867 on transport processes that electrified Boltzmann.

Are atoms real? If mass and diameter are primary qualities, yes - a reality suddenly unveiled in 1865 by J.J. Loschmidt from data on free paths and condensation-ratios. Here we must repudiate the myth that atomism had no physical basis prior to Einstein's and Perrin's work around 1905. The evidence was overwhelming. Maxwell's 1873 treatment (reprinted in 1890: 343-50) was the best, yielding estimates for molecular masses and dimensions, and Avogadro's number, remarkably near modern values.

Maxwell had found, and Boltzmann elaborated, a most surprising statistical law, the equipartition theorem. It gave for specific heats of gases unequivocally wrong answers. Classical mechanics had failed. Reviewing and rejecting in 1875 all the supposed explanations, Maxwell could only urge that ' thoroughly conscious ignorance which is the prelude to every real advance in knowledge' (1877b).

Since 1925 many people have made quantum uncertainty the door to human free will. Randomness spells choice. Years earlier, Maxwell in an essay on 'Science and Free Will' (1873; Campbell and Garnett 1882: 434-44) explored similar thoughts as issues of analogy. There is science, there is life. Planetary orbits are exactly predictable; gas laws statistically so; other phenomena not at all because tiny changes in initial conditions produce through instability vastly different outcomes. That in essence is chaos theory (see Chaos theory). Not every outcome is chaos, however. Human achievement lies in seizing such singular points, such 'tides in the affairs of men', and our deepest intuitions of free will connect with them. If that only advances us one step (elsewhere Maxwell said, 'states of the will only puzzle me' (1879; Campbell and Garnett 1882: 417)), it is a useful step.

Who but Maxwell would dare the inversion of basing physics on free will? Picking and choosing between fast and slow molecules, Maxwell's demon (in his *Theory of Heat* 1871) uses intelligence rather than work to transfer heat from cold to hot bodies, thereby defeating the second law of thermodynamics. Maxwell thus made entropy incomplete knowledge, refuting attempts by Clausius and Boltzmann to interpret it dynamically. Later (in 1877) Boltzmann derived a famous equation relating entropy to statistical disorder. In 1929 Leo Szilard sought exorcism through information theory, arguing that the demon's ordering of the world is outweighed by a quantum mechanical disordering within his own brain.

4 Relativity, reality, ether

Maxwell's philosophical position is best described as modified scientific realism (see Scientific realism and antirealism). Fundamental to it is Hamilton's distinction between knowledge and belief. Scientific knowledge is real but also limited, partly of the 'rigid high' kind, partly empirical, complicated by analogy, entangled in relations. A way through is classification, or rather multiplicity of classification. It is instructive to compare Maxwell's youthful essay 'Analogy' (1856; reprinted in Campbell and Garnett 1882: 235-44) with two later works, *Matter and Motion* (1877a) and the short 'Note on the Classification of the Physical Sciences' (1873; published 1884). By the 1870s he had defined a programme of dynamical reductionism which, except in its clarity and philosophical restraint, is strikingly modern. *Matter and Motion* is a masterpiece of natural philosophy,

notable especially for introducing into physics the term *relativity* in a passage that combines strenuous scientific insight with a mystical awareness worthy of the fourteenth-century author of *The Cloud of Unknowing*.

Relativity now connotes Albert Einstein. But the issues originated with Maxwell. He suggested the famous Michelson-Morley ether-drift experiment, and his equations necessitate the Lorentz transformation. About the ether Maxwell's problem was again knowledge versus belief. He accepted the ether; he did not finally describe it. His theory is a relational one. For him the ether had also another kind of relativity: it belonged to ' the science of 1876 (which may not agree with that of 1896)'. ([Letter to Bishop C.J. Ellicott, 22 November 1876] Campbell and Garnett 1882: 393) (see Relativity theory, philosophical significance of).

McTaggart, John McTaggart Ellis (1866-1925)

McTaggart was one of the last of the 'British Idealists', the group of British philosophers, such as B. Bosanquet and F.H. Bradley, who took their inspiration from Hegel. In his early writings from the 1890s, McTaggart gave a critical exposition of themes from Hegel's logic before advancing his own distinctive idealist positions concerning time, the mind, and reality in general. But in his writings from 1910 he developed an independent account of the structure of existence from which he then argued for the same idealist positions as before.

The thesis for which McTaggart is now most famous is that of the unreality of time; what is even more difficult to come to terms with is his thesis that the ultimate reality of the world comprises a community of selves wholly constituted by their loving perceptions of each other. This thesis is a manifestation of a mysticism that is an essential element in McTaggart's philosophy; yet this mysticism is combined with a rationalist determination, reminiscent of Spinoza, to vindicate mystical insights by the light of pure reason alone.

1 Hegelian dialectic

John McTaggart Ellis McTaggart's curious name arises from the fact that his father, Francis Ellis, having named his son 'McTaggart' after an uncle of that name, then took the name himself as a surname in order to inherit his uncle's wealth, and thereby passed the name again to his son. McTaggart studied at Cambridge and then taught there throughout his life. In his first work, *Studies in the Hegelian Dialectic* (published in 1896 but largely based on his 1891 Fellowship Dissertation), he defends the use of the Hegelian dialectic as the primary tool of philosophical argument. According to McTaggart, the great strength of Hegel's dialectic is that, by starting from minimal presumptions about the concepts to be applied on the basis of experience, it is possible to unravel significant conclusions concerning the structure of that which experience reveals - reality itself (see Hegel, G.W.F.).

McTaggart's emphasis on the dialectical method is indicative of the fact that he seeks to base his metaphysics on premises that are in a broad sense 'logical'. But he also thinks that there is something essentially mystical about the truths of metaphysics. These two fundamental presumptions of his philosophy are held together by the fact that he holds that the dialectical method itself leads one to recognize the fundamental reality of a domain which transcends ordinary experience. Following Hegel, McTaggart calls that which is thus fundamentally real 'The Absolute', but goes on to make it clear that his detailed conception of the Absolute is not that of Hegel. Thus he insists that the Absolute is not the culmination of a historical process, since the dialectic is not a temporal process whereby the Absolute realizes itself in the world - it is only a method of reasoning whereby we make explicit to ourselves what has *always* been the only fundamental reality. Instead, McTaggart argues in his *Studies in Hegelian Cosmology* (1901), the Absolute comprises a community of selves wholly occupied in loving perceptions of each other; for only within a structure of this kind are the formal requirements of the dialectic fully satisfied. It is not easy to follow McTaggart's reasoning on this issue, and even more difficult to grasp how one can suppose that the loving perceptions of such a community are, in fact, absolutely the only things that there really are. But the challenge of explaining himself on these issues is, in effect, that to which McTaggart dedicated the rest of his life (see Absolute, the §1).

2 Time

The thesis of the unreality of time is one that McTaggart endorses in his early Hegelian writings. In 1908, however, he published a paper on 'The Unreality of Time' in which he argued for this thesis from an independent starting-point.

He starts from the fact that we have two ways of indicating the time of an event such as the Battle of Hastings: we can either just indicate its relation to present experience, by noting that it is in the past; or we can give its date - 1066 AD - and thereby indicate its relationship as earlier or later than the event which is taken as the origin for the system of dates. Where events are ordered in accordance with a system of tenses McTaggart says that they form an 'A-series'; where they are ordered by a system of dates he says that they form a 'B-series'. The first part of his argument is intended to establish that the A-series is more fundamental than the B-series to the conception of such series of events as a series ordered in time. McTaggart argues first that change is essential to time and that while

the A-series conception includes change (in so far as that which was future becomes past), the B-series relations are immutable; second, he argues that time is essentially directed from past to future in a way which involves the A-series but not the B-series. The second part of McTaggart's argument revolves around the claim that the A-series does not after all provide a coherent temporal ordering of events: for the way in which the A-series allows for change leads to the contradiction of supposing that one and the same event is both past and future. Hence, McTaggart concludes, neither A-series nor B-series yields a coherent conception of a temporal ordering of events, and we must conclude that our very conception of events as ordered in time is illusory. In reality, the events are ordered in some other way (as the 'C-series'), and it is this real ordering which we erroneously perceive as a temporal ordering.

McTaggart's critics maintain that the appearance of contradiction inherent in the A-series arises only because McTaggart moves illegitimately from the coherent thought that the Battle of Hastings *was* future and *is now* past to the contradictory thought that it *is* (tenselessly) both future and past. McTaggart was aware of this response, but argued that the use of tenses here merely postpones the difficulty; for not only was the battle future, it was also present and past, so that the same contradiction arises even when tenses are used. Or does it? McTaggart's critics urge that it does not; and, further, that an A-series theorist need never assent to whatever combinations of tenses are incompatible.

Other critics seek to defend the status of the B-series. They argue that although the B-series does not allow for changes in the truth-value of judgments concerning temporal order, it does not follow that no conception of change can be included in such a scheme. Thus Russell (1903) urged that we can say that an object *a* has changed where the judgment that *a* has the property *F* at one date is true and the judgment that *a* has the property *F* at some different date is false. This is perhaps too simple, for it implies that things themselves change when, for example, people alter their attitudes to them; but if some restriction is placed on the relevant properties *F* that occur here (for example, that they be such that losing or gaining such a property has immediate effects for the thing in question), Russell's account looks plausible. Similarly, McTaggart's other claim, that the B-series does not yield an account of the direction of time, is disputed by those who argue that the temporal structure of causation gives time its unique direction.

Whether one wants to be an A-series or a B-series theorist, then, it looks as though there are positions that are preferable to McTaggart's denial of the unreality of time. Perhaps the most commonly held position these days embodies a compromise: it is argued that McTaggart's mistake lay in not recognizing that these two conceptions of time are interdependent - in that the A-series captures the tensed temporal perspective of the subject which is an essential ingredient of practical thought, whereas the B-series captures the tenseless truth-conditions of these A-series judgments, which cannot be coherently captured in A-series terms (seeMellor 1981 for a classic statement of this position) (see Time §1).

3 Idealist metaphysics

McTaggart's 1908 discussion of time shows him already arguing for his idealist conclusions without direct reference to Hegelian dialectic. In 1910 he completed a critical study of Hegel's logic, *A Commentary on Hegel's Logic*, which, although not at all hostile to Hegel's method, revealed substantial defects in the details of his arguments. Hence, McTaggart realized, if he was to secure the idealist conclusions of his earlier work, he needed to find new foundations for them. This was the task that occupied him for the rest of his life, and which he brought to fruition in his final, two-volume work, *The Nature of Existence* (1921, 1927).

In the first volume, McTaggart develops three fundamental ontological principles which, he argues, are a priori conditions of any acceptable metaphysics. McTaggart's account of these principles is obscure, but we can identify them as: (1) the identity of indiscernibles; (2) the infinite divisibility of substances; (3) the principle of 'ontological determinacy' - that is, the principle that the properties possessed by a substance must be fully determinate. In the second volume, McTaggart then argues that these principles can only be satisfied if his previous idealist convictions are correct (see Identity of indiscernibles).

McTaggart's line of thought is best approached by considering why he thinks that material substances fail to satisfy his a priori conditions. His claim is that once one has satisfied conditions (1) and (2) by supposing that a material substance is infinitely divisible into ever smaller parts, each of which differs descriptively from any other

part, one will violate condition (3) since it will no longer be wholly determinate, at any stage in the division, just what properties a substance possesses - for the precise determination of these properties will depend on the properties of its distinct parts *ad infinitum*. There is much here that might be questioned, including each of McTaggart's principles; but it is worth noting in passing that although McTaggart denies the reality of matter ('the result is that matter is in the same position as the Gorgons or the Harpies'), he is quite explicit that he does not dispute the propriety of common-sense talk of hands and so on. So, *pace* G.E. Moore (1939), he cannot be refuted by a simple appeal to the propriety of such talk.

It remains to be seen why McTaggart thinks that a community of at least two selves does satisfy his a priori conditions. The key point is that he takes it that condition (2) is satisfied because perceptions are 'parts' of a self, and the possibility of indefinitely reiterated perceptions of perceptions constitutes, therefore, the possibility of infinite 'division' of a self. Because these ever more complex perceptions are generated by reiteration, condition (1) is satisfied; and he holds that condition (3) is also satisfied because the content of simpler perceptions does not depend on that of the more complex perceptions of perceptions which are their 'parts'. Solipsism is ruled out in favour of a community of selves and their mutual perceptions of each other because a self whose only 'part' was its perception of itself would not have a proper part at all and would therefore violate condition (2); whereas once two or more selves are introduced, each self will have perceptions of the other as well as of itself and thereby introduce a structure of mutually self-reflecting perceptions of perceptions which McTaggart calls 'determining correspondence' and which, he thinks, is the only structure that can satisfy his a priori conditions.

4 Error and love

Because McTaggart's account of this community of selves and their perceptions of each other is supposed to be an account of the only things that there really are, he holds that our ordinary experience is almost entirely erroneous or misunderstood. It is not just that we misconstrue our perceptions of our hands as perceptions of a material world; we also radically mistake the nature of our own experience. We seem to ourselves to have mental states other than perceptions; but in fact we have *only* perceptions - and these perceptions are *only* perceptions of selves and their perceptions. How, then, is this massive error possible?

The conceptual possibility of massive error of this kind is allowed for by the 'perceiving as' idiom: what are in fact just perceptions of selves and their perceptions are perceived as material objects, choices and the like. Furthermore, according to McTaggart, the illusion of time is the ground of these errors. This illusion rests on our misperceiving the ordering of the members of the timeless C-series (which can only be selves and their perceptions) as a temporal ordering. McTaggart expends much ingenuity in setting out the structure of this C-series and suggesting how, once the illusion of time arises, other errors follow; but he acknowledges that he can give no reason why the illusion arises in the first place (in *Studies in the Hegelian Dialectic* he had observed that even the appearance of evil and error poses a deep challenge to the Hegelian dialectic; the deep reason for his abandonment of that method was probably a growing conviction that this challenge is unanswerable).

What, finally, of love? McTaggart's basic thought is that love is the emotion which manifests a sense of intimate union with a self; and since perceptions of ourselves and others provide precisely this sense of intimate union, the community of mutual perceivers is also a city of love. But there is also an element of residual Hegelian teleology here. McTaggart acknowledges that our ordinary perceptions of each other rarely, if ever, give rise to the appropriate sense of intimate union, but he looks forward to a kind of immediate awareness of others which resembles our awareness of ourselves. This possibility requires, however, an extension to our lives, a kind of immortality whereby we exist indefinitely into the future - or rather throughout the C-series, which we mistake for time. At the final stage of this series, McTaggart holds, all perceptions will be clear and distinct; hence here at last the city of love will be realized. We are not now at this stage, for the C-series is real and progress along it appears to us as the passage of time; but in the final ecstatic sentences of *The Nature of Existence* McTaggart looks forward to this ultimate consummation:

> We know that it is a timeless and endless state of love - love so direct, so intimate, and so powerful that even the deepest mystic rapture gives us but the slightest foretaste of its perfection.

(1927: 479)

Mead, George Herbert (1863-1931)

Together with Charles Peirce, William James and John Dewey, George Herbert Mead is considered one of the classic representatives of American pragmatism. He is most famous for his ideas about the specificities of human communication and sociality and about the genesis of the 'self' in infantile development. By developing these ideas, Mead became one of the founders of social psychology and - mostly via his influence on the school of symbolic interactionism - one of the most influential figures in contemporary sociology. Compared to that enormous influence, other parts of his philosophical work are relatively neglected.

Mead was the son of a Protestant clergyman in Massachusetts. He spent the larger part of his childhood and youth at Oberlin College, Ohio, where his father was appointed professor and where he himself studied. After four years of bread-and-butter employment and intense intellectual struggle with the Darwinian revolution and Kant's moral philosophy, Mead entered graduate study at Harvard and continued at the Universities of Leipzig and Berlin, Germany, specializing in questions of psychology and philosophy. After teaching at the University of Michigan (1891-4), Mead was brought by Dewey to the newly founded University of Chicago where he taught until the end of his life in 1931. Publishing very little, but increasingly influential through his teaching and his life as an activist citizen during the Progressive Era, Mead's reputation has grown since his death. All his major works were published posthumously, based partly on student notes, partly on unfinished manuscripts from his remaining papers.

Mead's intellectual development and general outlook are quite similar to Dewey's: from neo-idealism to a pragmatism oriented to the emerging social-scientific disciplines and the debates about the fate of the democratic ideal in fully industrialized societies. Mead went beyond Dewey in his theory of the specificities of human communication and sociality. Human communication is, according to Mead, superior to animal forms of communication primarily because it operates through 'significant symbols': human beings are able to react to their own gestures and utterances in a way that is anticipatory and thus inwardly represents their fellow 'actors'' possible responses. This makes it possible for their own behaviour to be oriented towards the potential reactions of other actors. As these actors, too, are in possession of this ability, common collective action oriented towards a common binding pattern of mutual behaviour expectations becomes possible. This is for Mead the fundamental feature of all human sociality. 'Taking the role of the other' - one of Mead's famous expressions - is the anticipation of the other's behaviour in a specific situation of interaction.

The possibility of communication through the inner representation of the other's behaviour leads to the formation of different instances in the personality structure of the individual. This is due to the fact that individuals observe and estimate their own behaviour similarly to the way they see the behaviour of partners. The individuals are able to look at themselves from the perspective of the other. Alongside the dimension of impulses there is now an opportunity to evaluate those impulses, an instance which arises out of the expectations of the reactions caused by the manifestations of these impulses. In this context Mead speaks about 'I' and 'me'. The concept of the 'I' designates not only the principle of spontaneity and creativity, but also the endowment of the human being with impulses. 'Me' refers to my own mental presentation of the other's image of me, or, on a more primitive level, to my internalization of the other's expectations of me. The 'me' is both an instance of judgment for the structuring of spontaneous impulses and an element of my emerging self-image. As I face several different persons who have significance for me, I acquire several different 'me' images. These have to be synthesized to make a consistent self-image possible. A successful synthesis generates the 'self' as a unitary self-evaluation and as an orientation for action. Simultaneously, a personality structure develops which is stable and certain of its needs.

Mead's ideas about the development of the self can be found *in nuce* in his theory of children's play. Therein, he draws a line between 'play' and 'game'. 'Play' means the child's playful interaction with an imaginary partner in which the child mimes both parts of the interaction. Thereby the capacity for anticipation of behaviour is given practice: the other's behaviour is represented directly, for example, via imitation, and is complemented by the child's own behaviour. The child has reached this stage as soon as it is able to interact with different persons; that means, when the person with a cathectically high significance is no longer the solely important one. This stage of development is followed by the attainment of the ability to participate in 'games', that is, group activities. In

'games' it becomes necessary that the behaviour of all partners - and not of one single partner - can be taken as the guideline for the child's action. The individual actor has to self orientate to a goal that is valid for all the actors concerned, and which Mead calls, trying to express its psychological bases, the 'generalized other'. In the case of games the generalized other's expectations of behaviour are the rules of the game; in general it means the norms and values of a group, differentiated in a specific way to take into account the specific positions in the group and specific situations. The orientation to a particular generalized other, however, reproduces on a new plane the same restriction which the orientation to a particular concrete other has. Thus follows the problem of an orientation to an ever more universal generalized other.

Mead further developed his ideas about human communication in the fields of general cognitive and moral development. The development of communicative abilities becomes a condition for cognitive progress inasmuch as it is the development of role-taking ability that allows the actors to assume a reflexive attitude towards themselves, and substantial cognitive achievements presuppose just such an attitude. Mead elaborates this idea in his late works, particularly with respect to the problem of the constitution of the permanent object. Its ethical implications are expounded at the individual level as universal role-taking ability and performance, and, at the societal level, in a concept of an ideal society with a universal capacity for communication. During the last decade of his life, Mead was particularly engaged in a dialogue with Dewey and Whitehead's new metaphysics and the role of sociality within it (see Dewey, J. §3; Whitehead, A.N. § 3).

Meaning and communication

The two fundamental facts about language are that we use it to mean things and we use it to communicate. So the philosophy of language tries to explain what it is for words and sentences to mean things and also what it is for us to communicate by using them. Although it cannot be accidental that meaning and communication go together, it is quite easy to see them as fundamentally distinct. Thus on some accounts the meaning of sentences is conceived in terms of a 'representative' power whereby they stand for either aspects of the world or ideas in the mind and their use in communication is derived from this property: language serves as a vehicle for meaning, itself thought of in independent terms. An alternative approach seeks to link the two more closely, seeing representation as itself only possible through the use of terms of a common language, used in communication.

At its most primitive, communication may be simply akin to infection, as when one animal communicates fear or hostility to another. Simple signalling is also described as communication, as when bees communicate the direction and quantity of pollen to other bees, or when birds communicate territorial or sexual claims. Here the signaller issues a sign and the recipient modifies its behaviour upon perceiving it; the content of the signal is interpreted (by us) to be whatever goal seems to be served by issuing it: maximizing the success of the hive in obtaining honey, or keeping other birds out of a particular space, for example. Humans communicate in a similar sense, through the use of emotional and other signals, unconscious 'body language' or equally unconscious or semiconscious signs, which may include fashion statements or indications of status, for example. When we communicate successfully we share an understanding. Everything is open between us; nothing is concealed nor taken by one person in one way and another in a different way. With linguistic communication this common understanding can be put in terms of meaning: we each know what the other means. This implies that we understand not only the semantics of the utterance, but also the pragmatics: if the utterance states that something is the case then we know what this is, but we also know if the statement was meant ironically, or condescendingly, or with some other intent (see Pragmatics). It is plausible to think that the basic goal of speech is to achieve such communication, although there will be cases where we speak in order to conceal our thoughts, or to mislead the hearer. People fluent in the same language achieve open communication more or less effortlessly, at least where straightforward messages are concerned. But philosophers of language have not found this phenomenon easy to understand. Issues arising include: the place of intention in communication (see Communication and intention); the place of linguistic convention in communication (see Language, conventionality of); the relationship between shared understanding and activities such as translation and interpretation (see Radical translation and radical interpretation); the pervasive possibility of indeterminacy; and the nature of rules and the extent to which language is essentially social - and indeed the extent to which language is necessary to communication (see Meaning and rule-following). In the analytic tradition, major writings on this subject include works by Wittgenstein, Grice, Lewis, Bennett, Kripke, Searle and Tuomela, while a more continental interest in the field is especially illustrated by Habermas (1984, 1987).

The classical tradition, including Aristotle, Hobbes and Locke, thinks of communication in terms of one party having an idea then using language as a medium for transmitting it to others. The meaning of the linguistic vehicle is then derived from the primitive representative powers of the idea. The analytic tradition has sought to bring our ability to represent things closer to our ability to express what we think linguistically, even to the point of reversing the dependency and making thought itself (or at least the kind of thought that could be expressed in language, unlike perhaps the thought of the graphic artist or the musician) dependent upon its linguistic expression. The question then becomes one of saying how language can generate 'intentionality', which is the power of being 'about' external and often absent situations which it represents truly or falsely (see Intentionality). If, for example, language is essentially a shared and social construction, and if it is necessary to thought, then we derive the result that a born Robinson Crusoe would not be capable of thought, at least until he acquired a social identity. The consequence seems uncomfortable, since it is easy to imagine such a Crusoe giving all sorts of signs of intelligent adaptation to his environment, and conceiving and executing complex plans. For some thinkers, such as John Searle (1983), this is because intentionality resides in our biological nature, in advance of and independent of language. For others, such as Jerry Fodor (1987), it is because we come equipped with an innate representative medium conceived on the model of a natural (social) language, but itself explaining the powers of natural languages: a 'language of thought' (see Language of thought).

Arguably too much of the theory of communication treats the process as one of interpretation or translation, in which the task of the hearer is to theorize about the thoughts intended by some act of communication of the speaker. This makes it seem as if each person is secure in their own 'ideolect', with it being relatively problematic whether the same ideolect is shared by others. This clearly distorts what it is to share a language, which surely entails finding ourselves (surprisingly literally) of one mind about meaning. We have a securely shared common understanding, in which I have no privileged access to my own meanings which is not communicable to others. Philosophers have therefore struggled against the vision of the infant, inducted into this shared language, as a kind of outsider or 'little linguist' busy theorizing (in what medium?) about the potential meanings of the utterances made by surrounding people. The proposed alternative derives from the *Verstehen* (literally 'to understand') tradition of humane sciences (see Dilthey, W.), seeing the task of the infant not so much as one of theorizing as one of imitating and simulating the expressions of others. I achieve the openness of full communication with you, on such an account, when I know what it would be to make your words my own.

Meaning and rule-following

Wittgenstein's discussion of rules and rule-following, and the recent responses to it, have been widely regarded as providing the deepest and most challenging issues surrounding the notions of meaning, understanding and intention - central notions in the philosophy of language and mind. The fundamental issue is what it is for words to have meaning, and for speakers to use words in accordance with their meanings. In Philosophical Investigations and Remarks on the Foundations of Mathematics, Wittgenstein explores the idea that what could give a word its meaning is a rule for its use, and that to be a competent speaker is to use words in accordance with these rules. His discussion of the nature of rules and rule-following has been highly influential, although there is no general agreement about his conclusions and final position. The view that there is no objectivity to an individual's attempt to follow a rule in isolation provides one strand of Wittgenstein's argument against the possibility of a private language.

To some commentators, Wittgenstein's discussion only leads to the sceptical conclusion that there are no rules to be followed and so no facts about what words mean. Others have seen him as showing why certain models of what it takes for an individual to follow a rule are inadequate and must be replaced by an appeal to a communal linguistic practice.

1 Meaning and rules

Words are meaningful only if there is such a thing as using them correctly or incorrectly. To have determinate meanings they must have application in some situations and not others. Words that had application to just anything would be robbed of meaning and could not be distinguished from one another. But what gives a word meaning? And how does this determine what uses do and do not comply with it? Answers to these questions must be compatible with a credible epistemology of meaning: when we understand a word we must be able to use it in accordance with its meaning. If something were to settle the right or wrong use of a term, we must be able to take cognizance of this. The objectivity of meaning and linguistic judgment depends on this. We have to secure both of these simultaneously.

In his later writings, Wittgenstein rejects the idea of meanings as mental or abstract entities to be associated with particular signs. Instead he takes the meaning of a sign, or word, to be its use in a language. However, in equating meaning with use he does not assume that every way of using a sign can contribute to its meaning. To have a meaning there must be some particular range of application that counts as using a word correctly. But what does the correct use of a word consist in? Wittgenstein explores the claim that a word is used correctly when it is used in accordance with a rule. If there are rules governing the use of words, then there are standards speakers have to meet to deploy words competently. Competence requires speakers to know what counts as applying the word correctly or incorrectly on any occasion. The appeal to rules is also thought to guarantee the range of things a word applies to: the rule can be thought of as settling the application of a term not only to cases considered so far, but also to hitherto undiscovered cases.

These features of rules bring out the normative element in meaning. Given that words have meanings there is something that counts as using them in accordance with these meanings: this is how words *should* be used. When meanings are given by rules of use, competent speakers are required to conform to these rules: a rule does not just describe the use we make of an expression, it says how we *ought* to use it.

To satisfy ourselves that there is some substance to the notion of meaning, we need to account for the nature of these rules and the requirements they impose on our correct use of words. We also need an account of how speakers succeed, if they do, in following these rules. The issues are connected. If no account can be given of what it takes to heed the requirements of a rule, it is hard to credit those rules with any normative force in determining the meanings of words in our language. On the other hand, the idea of us conforming our linguistic practice to the requirements of rules cannot be maintained if we can give no substance to the idea of there being rules to be followed in the first place.

2 Rules and rule-followers

Wittgenstein addresses the issue of what it is to follow one rule rather than another by considering the case of a

learner asked to continue the arithmetical series: 2, 4, 6, 8…. There are infinitely many options for them. They could go on by writing 10, 12, 14, or 10, 14, 18, and so on. All they are shown are finitely many cases and from there they must acquire the ability to continue the series the mathematician intended. To go on from any position to the next they need to know the rule for expanding the series. But how do they acquire that from their exposure to the examples? Wittgenstein reviews a number of models for such knowledge of rules, and rejects them as inadequate.

First, we might think of learners giving themselves an instruction (such as $n = x + 2$), which tells them what to do next. But no instruction is sufficient, since it can only be followed if the learners know what it means. If they know this, then we must ask in what their acting in accordance with the meanings or rules governing *that* instruction consists. Either we appeal to further instructions, thus setting up an infinite regress, or else we suppose they just know what the instruction means in which case we have no explanation of their understanding, and we are no further forward.

Perhaps a learner simply reacts to the presented cases in some way, and either does or does not satisfy the mathematician. But if this learner is simply caused to respond, we are unable to say what it is for them to go by the rule as opposed to merely reacting to instances of it. On a future occasion they could be caused to act in a way at odds with the intended series. Also, their reactions may be fortuitous: they may be fitting the rule but not following it, blind to what is required of them. Only if the learner and the mathematician follow the same rule is the possibility of coincidence neutralized.

The justification of each move, if there is one, will depend on the rule the learner is following. But which rule is this? There are infinitely many rules compatible with the learner’s behaviour so far, and every move they subsequently make can be made to accord with some rule or other. So what reason is there to think, before the learner decides on their next move, that there is some particular rule they are following? Perhaps we do not consult anything to decide how we are using a sign (or expanding a series). Nevertheless, the temptation exists to say that there must be something that determines whether we are going right or wrong in what we decide to do.

We might then say the rule itself determines right and wrong moves, because it consists in the full expansion of the series with all the instances fixed. As Wittgenstein puts it, it is as if all the steps had already been taken. This is a picture of rules as rails stretching ahead of us to infinity, with the rules fixed in some abstract or Platonic realm: what is required of us in any given application of them would thus be constituted wholly independently of human propensities to judge. The difficulty with this picture is that it gives us no idea of how we recognize which standards to conform to. If rules were blankly external to the mind, there would be no way to discover what they require of us. However we used words, whether or not we coincided with these objective standards would be a matter settled independently of us. Such a conception makes it unclear how such rules or standards could inform our practices, and it is hard to see how we could attempt to conform to rules that fall outside our cognitive reach.

The Platonist’s picture mislocates the normative dimension of speech. At best our judicious use of words would be a series of stabs in the dark with which we hoped to speak significantly by coinciding with the mind-independent meaning-facts. This picture may afford the idea of an objective standard for our linguistic judgments, but there would be no difference (from the point of view of the speaker) between observing this standard and following one’s subjective inclination to use the words as one felt fit. Without speakers being apprised of the standards of use that regulate their linguistic practice, meaning-scepticism would arise, putting in doubt both the existence of Platonized rules and the possibility of a speaker using words in accordance with their meanings. It seems as if the trouble with Platonism is that it locates the meaning-determining rules wholly outside the mind of the speaker.

Wittgenstein next turns to the temptation to find some self-interpreting item in the mind which serves to stop the regress of interpretations, and by itself points to the correct application of a word. Wittgenstein tells us that when we review the instructions we might give ourselves for deploying a word, it is as if meaning was the last interpretation. The trouble now is that there are no candidates for this role. If we suppose that the meaning itself is an item in mind, or that we have an intuition of what is required of us on any occasion of use, we need to know how such things as items in consciousness could point to the conditions of application for a word. For if intuition leads us to apply the word in one way, it could just as easily mislead us: we are simply reacting in a way that feels right. No items whose properties we can scrutinize consciously seem to carry the right information about how we should use a word, or comply with a rule in unexamined cases. It is utterly mysterious how anything we

consciously consult could do this. It might be said that knowledge of our intention in using the word will serve here, but this also proves unsatisfactory: we are trying to explain how we can have such an intention in the first place, and how we can tell whether or not we are conforming to it. The appeal to an inner item is thus no better than Platonism. Locating the item inside the mind has still not connected our use of a word to a norm we can appreciate and whose requirements we could take into account in our linguistic use.

We appear to have exhausted the options. Does this mean that when we judge how to use an expression there is nothing that counts as getting it right? To concede this would be to surrender the objectivity of linguistic judgments and settle for an absence of genuine constraints on how to use words. However we go on using a word in future, there would be nothing that counted as acting in accordance with the rules, since there would be nothing for the requirements of the rules to consist in. How could thinking about a rule show me what I was meant to do at this point? There may be a subjective impression of constraint, of going on in the right way. But is there anything this answers to? For any way I chose to use the word in a new case, can be made to conform to some rule or other. There are interpretations that can be made consistent with anything I do, as Wittgenstein tells us in *Philosophical Investigations*: 'any interpretation hangs in the air along with what it interprets, and cannot give it any support. Interpretations by themselves do not determine meanings' (1953: §198). If every way of employing a term can be made to conform to a rule, then 'whatever is going to seem right to me is right. And that only means that here we cannot talk about "right"' (1953: §258). Without a distinction between what 'seems right to me' and what *is* right in my use of language, there can be no objectivity to meaning.

This is the conclusion Saul Kripke sees Wittgenstein as reaching at §201 of *Philosophical Investigations*; a conclusion Kripke, in his influential reading of Wittgenstein, calls the sceptical paradox.

3 Kripke's Wittgenstein

As Kripke (1982) formulates it, the sceptical paradox arises for a subject who has already been using the symbol '+' satisfactorily to compute sums of numbers less than 57. Kripke's example supposes that they are then asked to add 68 and 57. They might answer '125', but what fact about them makes this the right answer? The challenge to the subject is to come up with a fact about previous mental, behavioural or physical history that constitutes meaning *plus* rather than the deviant operation *quus*: an operation which shadows addition until we reach numbers greater than 57 at which point the answers are not the sum of those numbers, but always 5. If they meant *plus* by '+', then they are right; if previously they meant *quus*, then to answer correctly they should have answered '5'. They are only justified in answering '125' if there is a fact about what they mean by '+', a fact about which rule they have been following until now and continue to follow.

For Kripke this is not an epistemological problem about there being certain facts to which we cannot have access. He allows the sceptic to suppose that a subject has perfect recall and access to their past behaviour, conscious experiences, memories and so on, but points out that they are still unable to come up with any fact that constitutes their meaning *plus* rather than *quus*. The failure to do so leads Kripke's sceptic to conclude that there is no fact of the matter about a subject's meaning one thing rather than another. There are simply no facts of the matter concerning meaning. (Though Simon Blackburn (1992) argues that this claim cannot be made in the first person without it being self-defeating since the person must be able to distinguish *plus* from *quus* to appreciate the problem.) Although Kripke takes this damaging conclusion to be the upshot of Wittgenstein's rule-following considerations, he suggests that Wittgenstein tries to show that we can live with the consequences. (For Kripke's presentation of what he takes to be Wittgenstein's sceptical solution, see §4.)

Crispin Wright (1989a) and John McDowell (1984) both challenge Kripke's reading of Wittgenstein. They point out that Kripke's sceptic is forcing us to provide a reductionist answer to the question of what my meaning *plus* rather than *quus* consists in. To substantiate the claim to mean one thing rather than another, we are asked to come up with some fact other than that we mean *plus*, or had the intention to use the word as we previously did. McDowell suggests there is no way to avoid an appeal to the fact that we meant *plus* by our words all along, and he insists that we have to take this as a stopping place for explanation. No justification of this fact can be given: we simply have to remind ourselves of the meanings we know our words to have. This approach has come to be known as quietism (see §5). Wright thinks we have to appeal to speakers' previous intentions concerning their use of the word to settle questions of justification, but unlike McDowell he believes there is a constructive explanation of what it is to know one's intentions and conform to them (see §6).

Wittgenstein's remarks at §201 of the *Philosophical Investigations* certainly suggest a sceptical paradox which gives rise to the dilemma McDowell identifies: either we have an item to provide the interpretation and are saddled with Platonism or a regress of interpretations, or in using words as I do I simply act blindly and there is no fact of the matter about what I mean. According to McDowell, the paradox depends on an assumption to be discharged: namely that meaning something by a word must be a matter of attempting to give it an interpretation. In the second half of §201, Wittgenstein goes on to suggest that there must be a way of meaning something that is not a matter of interpretation. This recommends a different way of construing the presence of rules in linguistic behaviour. In following a rule, the individual does not search for an interpretation. He just acts without giving himself supporting reasons. But unlike Kripke's reading, this does not lead to the conclusion that there is no fact of the matter about what a speaker means. We are told at §289, that 'To use an expression without justification is not to use it without right.' What is needed is an alternative account of what it is to act in accordance with a rule and to use our words correctly.

This is where the appeal to the community comes in. Rather than train our sights on facts about an individual, following a rule is a matter of participating in a communal practice. This retains the idea that there must be something that counts as acting in accordance with a rule or going against it on any occasion, but now conceives of it as a matter of obeying a practice or going against it. The idea of rules as consisting in communal practices leaves room for a number of different treatments of the way an appeal to the community can help here. These are reviewed in §4 as attempted solutions to the sceptical paradox, after discussion of another popular response to Kripke: the dispositional response.

4 Attempted solutions

Dispositional response. The dispositionalist attempts to respond to Kripke's sceptic by insisting that while no occurrent facts about a speaker's behaviour or mental history determine what they meant by their words, their disposition to respond in particular ways to cases when confronted by them settles the matter. The dispositionalist is here relying on the fact that when a thinker is asked what '$68 + 57$' is, they will be disposed to reply '125'. However, the disposition of the subject can be tested in only finitely many cases, whereas addition is defined over an infinite range. Also, the subject may not have the disposition to respond in the case of very large sums where the computations are difficult, and they may be disposed to make mistakes. These cases could be dealt with by pointing to a different set of dispositions to work out the sum on paper and to check the results. However, Kripke's main objection to the dispositionalist's solution is that it loses sight of the normative element of meaning. In each case, the dispositionalist tells us how we *would* respond but not how we *should* respond. If I am using a word in accordance with its meaning, there is a way in which I am obliged to use it if I want to apply it correctly. Kripke tells us that the dispositionalist simply equates correctness and performance.

Appeal to the community. One can perhaps resist the conclusion that there is no fact about what a speaker means by their words by bringing in a background of other users against which the use of a word can be measured. We could say that the speaker does attach a certain meaning to a word, if their use of it coincides with the way the majority of people in their linguistic community use it. This response parallels the dispositional response, except that it considers the dispositions of everyone in the linguistic community. The notion of correctness is established in this case not by appeal to a rule that the individual is following, but by appeal to a widespread pattern of use exemplified by fellow language-users. In so far as there is a fairly widespread and consistent pattern of use for a word, the individual will count as using a word correctly just in such cases as their use of the term coincides with this pattern. They need not know that it coincides, or even check that it does. On this view, a speaker's knowing what they mean will not be the effortless and direct matter it is for most people. For this speaker it will be a matter of determining their fit with the uses other people make of these words. We may submit to correction when a number of people point out how our use of a word diverges from theirs, but we can be offered no determinate advice on what is required of us in the future if we are to continue conforming to majority use. For at the community level, there is no fact of the matter about what we mean collectively or what rules we are following (see Wright 1980). The strategy establishes for each individual language-user a sense of their using words correctly or incorrectly, and to that extent determines some objectivity for their linguistic judgments, but the community itself does not go right or wrong, it simply goes. Such a strategy puts in doubt the existence of meaning for shared public languages. And as far as individuals are concerned, it does nothing to guide their use of language.

They will merely coincide or fail to coincide with their fellow language-users.

Kripke's sceptical solution. Kripke's sceptical solution invokes a different appeal to the community. Unlike a straight solution this in effect concedes that there is no answer to the sceptical paradox, but attempts to show us that we can live with the consequences. Kripke maintains that although there are no meaning-facts to settle how my words *should* be used, I will go on using them like other people and be subject to correction by them. Claims about what my words mean will lack truth-conditions but, Kripke insists, they will have assertion-conditions: conditions under which people will be prepared to assert that someone is using a word in conformity with its meaning. There will be nothing about someone's use of a word to which this claim is answerable, but there will be uses we have for such statements that do not require their truth. There is no such thing as individuals taking themselves to mean something in isolation from the community, since there would be no background consensus to establish even assertion-conditions for claims about what they mean. The consensus depends on a community, so the appeal to the community rules out the possibility of someone using a private language.

The sceptical conclusion has been resisted by those who maintain that it is part of Wittgenstein's aim to defuse rather than accept the sceptical paradox. The paradox arises, it is claimed, because of a mistaken understanding of what is required to follow rules competently.

5 McDowell's quietism

As long as there is something that counts as obeying a practice or going against it on any occasion, there is such a thing as correctly following a rule. Rules will no longer be thought of a something I consult inwardly, or by reference to which I interpret what is required of me. Rather, they will simply be enshrined in our practices - the normative practices which inform our linguistic behaviour and impose constraints on the meaningful use of our terms. Individuals follow rules when they participate in communal practices. It has to be by reference to this notion of practice, that our judgments about how to use words come to have objectivity. So what is a practice and how does it provide for the idea of going right or wrong on any occasion?

The simple idea of *de facto* conformity with others cannot serve here. For according to that conception, being right in our use of a word is just a matter of whether we find ourselves in agreement with the majority, and this threatens to deprive the picture of its normative dimension (see §4). How can whether I am in step with my community determine how I should go on using and understanding a term? How can this show me how I ought to use language to be faithful to the meanings of my words?

What we need is to restore the idea of a community of speakers who operate according to the norms of meaning. John McDowell (1984) insists that such a picture is available to us when we observe Wittgenstein's warning not to try to dig below bedrock (the level, Wittgenstein says, at which justifications give out). We can dig down to the ground to find justifications but we will reach a level where no further explanation can be given by reference to what goes on at the level below. This is bedrock. McDowell characterizes bedrock for our linguistic practices as a level of activity at which norms are still in place, and where we must describe one another's linguistic behaviour in the meaningful terms available to us as speakers of the language in question. We will have to describe people's activities as 'saying that *such and such*' - where the words we use to describe what is said (*such and such*) are the very words used by the speaker. This kind of description will not be intelligible to those outside the practice.

This is a resolutely anti-reductionist approach to meaning and rule-following, and we are told that we can expect no explanations of meaningful speech and linguistic practice by reference to something else. We simply have to remind ourselves how familiar we are with the meanings of our words and what they require of us in so far as we participate in these normative practices. No explanation can be given of their significance, and none is called for. This position known is as quietism.

6 Wright's extension-determining approach

Crispin Wright (1989a) opposes both quietism and the sceptical paradox, believing that there is room to show what the rule-governed meaning-facts consist in. Wright accepts the challenge to show how it can be that the requirements of rules governing our words are not simply up to us, while it is also true that they are not constituted wholly independently of us. The aim is to avoid surrendering the objectivity of meaning while at the same time bringing it within epistemic reach.

Wright argues that what constitutes a correct application of a word, including its application to a new case, and how it was used previously, is not something that can be settled independently of human judgment. A contribution from us is required to settle the matter. Wright avoids a slide to subjectivism by claiming that our best opinions about what we previously meant or intended will settle the matter, and since not every opinion we form is best it is not true that whatever we judge to be right is right. Only those judgments we make in the most propitious conditions for judging go into determining the right use of a term. The key point is that our linguistic judgments under these conditions *determine* rather than *reflect* the correct application of our terms. These judgments about how to use words do not involve a tracking epistemology: we are not keeping up with Platonic standards or internalized instructions. According to Wright, if we can specify cognitively ideal circumstances for judging in a substantial and non-circular way, then there is nothing but our opinions in those circumstances to decide what we mean by these words. In this conception, meanings are like secondary qualities. Objections to this account question the plausibility of giving a non-circular specification of the ideal circumstances for judging meanings or conditions of application.

Meaning and truth

Analytic philosophy has seen a resurgent interest in the possibility of explaining linguistic meaning in terms of truth, which many philosophers have seen as considerably more tractable than meaning. The core suggestion is that the meaning of a declarative sentence may be given by specifying certain conditions under which it is true. Thus the declarative sentence 'Venus is red' is true just in case the condition that Venus is red obtains; and this is exactly what the sentence means.

As it stands, however, this suggestion provides us with no explanation of the meanings of the words and phrases that make up sentences, since in general they are not expressions that have truth-conditions. (There are no conditions under which the word 'Venus' is true.) Furthermore, it needs to be supplemented by some method of circumscribing the truth-conditions that embody the meanings of declarative sentences, since there are many conditions under which any given sentence is true: 'Venus is red' is true not merely when Venus is red, but also, for example, when Venus is red and 7 + 5 = 12; but it does not mean *that Venus is red and 7 + 5 = 12.*

Evidently the first problem can be solved only by finding other semantic properties which indicate the meanings of words and phrases. For example, it is sometimes thought that the meaning of a name can be specified by saying what it refers to; and that of a predicate by saying what it is true of. But notice that since the meaning of a declarative sentence can be grasped by first grasping the meanings of its basic components, meaning-indicating ascriptions of semantic properties to those components must entail a meaning-indicating statement of its truth-conditions. Semantic properties such as 'referring to' and 'being true of' satisfy this requirement, at least in the context of what is sometimes called a 'truth theory' for a language.

This still leaves the problem of how to circumscribe the right meaning-indicating statement of truth-conditions for declarative sentences. Indeed we now have a further problem. For if the meanings of the components of sentences are not stated directly, but merely in terms of what they refer to or are true of (say), then we must also find a way of determining which of the many ways of specifying what they refer to, or the conditions under which they are true of something, is meaning-indicating. These problems may arguably be solved by placing an appropriate truth theory for a language in a setting that allows us to appeal to the general psychology of its speakers.

Attempts to elucidate meaning in terms of truth-conditions induce a plethora of further problems. Many are a matter of detail, concerning the kinds of properties we should associate with particular idioms and constructions or, equivalently, how we are to produce truth theories for them. As a result of Tarski's work, we have a good idea how to do this for a wide range of categories of expressions. But there are many which, superficially at least, seem to resist straightforward incorporation into such a framework. More general difficulties concern whether truth should be central at all in the analysis or elucidation of meaning; two objections are especially prominent, one adverting to antirealist considerations, the other to the redundancy theory of truth.

1 The core suggestion and some problems

Three of the most influential approaches to the understanding of linguistic meaning in contemporary analytic philosophy correspond to three different, though overlapping, roles of language: its role in communication; its role in reasoning; and its role in making statements. According to the first of these approaches, linguistic meaning should be analysed or elucidated in terms of the communication intentions of speakers (see Communication and intention; Meaning and communication). According to the second, it should be characterized in terms of the conceptual or inferential role of expressions of the language (see Semantics, conceptual role). And the third, at least in the form in which it has been most fully articulated, requires meaning to be analysed or elucidated in terms of the truth-conditions of sentences whose characteristic role, at least in context, is to make statements. It is the third approach which is the subject of this entry.

The core suggestion (which we owe to Frege (1964)) is that the meaning of a declarative sentence is given by certain conditions under which it is true. Thus 'Venus is red' is true just in case Venus is red; and that Venus is red is precisely what the sentence means. However, this fact leaves us in the dark about the meanings of expressions which are not sentences. For example, none of the words that makes up the sentence 'Venus is red' is the kind of expression that can have truth-conditions. Furthermore, there are countless other conditions under which the

sentence is true that do not reveal its meaning - that Venus is red and $7 + 5 = 12$, for example. So the core suggestion must be supplemented not only by some way of articulating word meaning, but also by a method of picking out those truth-conditions of declarative sentences that embody their meanings - a method which does not make reference to meaning itself. I shall call the problem of articulating word meaning ‘Problem A’, and the problem of picking out the right truth-conditions of sentences ‘Problem B’.

Let us begin with Problem A. It is clear that to solve it we must find further semantic properties which can plausibly indicate the meanings of non-sentential expressions, just as particular truth-conditions are meant to indicate the meanings of declarative sentences. For example, it is plausible to claim that the meaning of a name can be specified by saying what it refers to, and that of a predicate by saying what it is true of: the meaning of the name ‘Venus’ may be specified by stating that its referent is Venus; and that of the predicate ‘is red’ by stating that it is true of something if and only if that thing is red.

However, two difficulties arise with this proposed solution to Problem A. The first - which I shall call D(i) - is an analogue of Problem B. This is that there are many ways of stating the referent of a name, and many ways of stating what predicates are true of, but not all of them are meaning-indicating. Thus, although we may say that the referent of ‘Venus’ is Venus, we may also say that it is Hesperus, or the thing that is both Venus and either green or not green; but only the first statement of its referent specifies its meaning. Equally, although we may say that ‘is red’ is true of something if and only if that thing is red, it is also true of something if and only if the thing is red and $2 + 2 = 4$, and so on; but again only the first biconditional specifies its meaning.

The second difficulty, D(ii), arises from the fact that anyone who understands the components of a given sentence is generally in a position to understand the sentence itself; no further information is needed. For example, if I understand both ‘Venus’ and ‘is red’, I can immediately go on to understand the sentence ‘Venus is red’. Now this is tantamount to saying that the meanings of sentences are determined by the meanings of their components (see Compositionality). Thus the meanings of ‘Venus’ and ‘is red’ determine that of ‘Venus is red’. But if this is right, then any correct specifications of the meanings of a sentence’s components should entail meaning-indicating statements of the truth-conditions of the sentence itself. In particular, the specifications of the meanings of ‘Venus’ and ‘is red’ should entail the meaning-indicating statement of the truth-conditions of ‘Venus is red’, namely that ‘Venus is red’ is true if and only if Venus is red. (If not, the putative meaning-specifications of ‘Venus’ and ‘is red’ must have left something out.) The problem, however, is that even in this simple case it is not immediately clear how to ensure this.

2 Truth theories

It is convenient to tackle difficulty D(i) after we have dealt with D(ii). We can then deal with D(i) along with Problem B (the corresponding difficulty for sentences). Turning to D(ii), then, how are we to ensure that correct meaning-specifications for a sentence’s components entail a correct specification for the sentence itself? Here it is customary to appeal to what is often called a ‘truth theory’ for a language. For it is precisely by employing such a theory that statements of truth-conditions of sentences of a language can be deduced from statements about the semantic properties of their components (see Tarski, A.).

What is a truth theory for a language? Ordinarily, it is taken to consist of three parts: syntactic, semantic and logical. The syntactic part comprises a set of clauses stating how sentences of the language are constructed out of the vocabulary of the language. These clauses allow us to construct a description of any sentence of the language which shows how it is composed out of its vocabulary. (Such descriptions are often called ‘structural descriptions’.) For example, in a very simple subject-predicate language - call it *L* - whose vocabulary consists of the English names ‘Venus’ and ‘Polaris’ and the English predicates ‘is red’ and ‘is bright’, four sentences are constructible. Letting ‘ $x^\wedge y$’ mean the result of concatenating *x* with *y*, we may describe these sentences structurally as follows: ‘Venus’ $^\wedge$ ‘is red’, ‘Polaris’ $^\wedge$ ‘is red’, ‘Venus’ $^\wedge$ ‘is bright’ and ‘Polaris’ $^\wedge$ ‘is bright’. (This notation is rather clumsy, so, for ease of reading, I shall use quotation marks both in the ordinary way and to indicate structural descriptions.)

Next, the semantic part comprises a set of clauses specifying various semantic properties of the vocabulary of the language, together perhaps with a number of semantic properties of complex expressions articulated as a function of the semantic properties of their components. In tandem with the third part, which consists of a number of logical

and set-theoretic principles, these clauses will determine the truth-conditions of sentences of the language. It is this last feature that allows us to see in principle how we might solve D(ii).

Consider the language *L* again. Our aim is to find semantic properties of its names and predicates which will determine the truth-conditions of sentences containing them. And if what we have said so far is right, this should involve a statement of what (according to the theory) the names refer to and the predicates are true of. Thus we might have

(1) The referent of ‘Venus’ = Venus;
(2) The referent of ‘Polaris’ = Polaris;
(3) ‘is red’ is true of something iff that thing is red;
(4) ‘is bright’ is true of something iff that thing is bright.

(Note that strictly speaking the semantic properties here should be relativized to *L*, for in other languages its names and predicates may refer to or be true of very different things. Suppressing the language parameter, however, makes the axioms more readable. The same is true of all semantic properties considered in this entry.)

At this point, of course, we still do not know how these clauses determine specific truth-conditions for sentences. But we may remedy this by adding the following general clause relating the truth of *L*-sentences to the semantic properties of their components:

(5) For all names γ and predicates *F*, ‘ γF’ is true if and only if *F* is true of the referent of γ.

For assuming that the third, logical part of the truth theory includes elementary first-order logic, it is then a simple matter to deduce truth-conditions for the sentences. For instance, we may easily deduce that ‘Venus is red’ is true if and only if Venus is red. For (5) will entail that

‘Venus is red’ is true if and only if ‘is red’ is true of the referent of ‘Venus’;

(1) will entail that

‘is red’ is true of the referent of ‘Venus’ if and only if ‘is red’ is true of Venus;

and (3) will entail that

‘is red’ is true of Venus if and only if Venus is red.

Similar reasoning will enable us to deduce that ‘Polaris is red’ is true if and only if Polaris is red, and so on for the other two.

We are thus able to deduce a statement of what are in fact meaning-indicating truth-conditions for each of the sentences of *L* on the basis of axioms which assign semantic properties to their components, along with a further axiom which characterizes their modes of combination. Of course, this only solves our difficulty for the very limited language *L*; but it does give a hint of how to solve it more generally.

3 Providing correct meaning-specifications

Let us turn now to Problem B - how to circumscribe in a non-circular manner those truth-conditions of declarative sentences which embody their meanings - together with D(i), the corresponding problem for sentence components. And let us begin by introducing a common abbreviation: let us call a biconditional of the form ‘*S* is true iff *p*’ a ‘*T*-sentence’. Since *T*-sentences evidently express the truth-conditions of the declarative sentences mentioned on their left-hand sides, it follows that to deal with Problem B, we need a non-circular way of singling out those *T*-sentences which genuinely indicate the meanings of the declarative sentences from those which do not. One suggestion would be to require that for ‘*S* is true iff *p*’ to be a meaning-indicating *T*-sentence, ‘*p*’ must be a translation of *S*. But although this would certainly ensure that the *T*-sentence correctly indicated the meaning of the relevant sentence, it would not provide a non-circular elucidation of its meaning, since the notion of translation itself directly presupposes the notion of meaning: when *A* and *B* are distinct expressions, *A* is a translation of *B* if and only if *A* and *B* have the same meaning.

A second suggestion is to replace the notion of translation with more general anthropological considerations relating to interpretation. Speech and writing are activities which take place against a backdrop of broadly rational activity, and can be interpreted in the light of such activity with a view to making maximum sense of speakers' behaviour. Consequently, it should be possible in principle to determine whether speakers are saying, for example, that Venus is red when they utter a particular sentence *S* by assessing whether that would be the most sensible thing for them to be saying in the circumstances, and in the light of all their other behaviour. And if this is what they typically or characteristically say when they utter *S*, then (according to the second suggestion) we may identify this with the appropriate truth-condition for *S*.

This prompts the following thought: '*S* is true iff *p*' is correctly meaning-indicating if, other things being equal, the supposition that speakers are saying that *p* in characteristic utterances of *S* makes maximum sense of their behaviour. But even this might be thought to invite a similar criticism to the one which undermined the first suggestion. For does not the use of speech acts such as saying just bring in meaning by the back door? It certainly seems to if saying that *p* is uttering something that means that *p*. But much depends on whether a deeper account of saying - and other speech acts - is possible (see Radical translation and radical interpretation).

A third suggestion would be to forgo such use of speech acts in the characterization of meaning, and focus on speakers' knowledge of truth-conditions. It is clear that those who understand the sentence 'Venus is red' will know not merely that 'Venus is red' is true if and only if Venus is red, but that speakers are expected to know this. Moreover, it also seems clear that they will know that this is the strongest thing speakers are expected to know about the truth-conditions of 'Venus is red'. They will know, for example, that speakers are not expected to know that 'Venus is red' is true if and only if Venus is red and $7 + 5 = 12$. But this suggests the following proposal: that '*S* is true iff *p*' is meaning-indicating if any speaker knows that *S* is true if and only if *p*, that speakers are expected to know this, and that this is the strongest thing speakers are expected to know about the truth-conditions of *S*. Our *T*-sentence which fails to specify the meaning of 'Venus is red' - 'Venus is red' is true if and only if Venus is red and $7 + 5 = 12$ - is then ruled out (see Meaning and understanding).

Turning now to D(i), what of the components of sentences? How can we ensure that their meaning-specifications are correct? A thought that has occurred to several writers is to let whatever is the most satisfactory method of circumscribing the meaning-specifying truth-conditions of sentences do all the work: to say, for example, that the meaning of a non-sentential expression of a language can be specified by its clauses in any true truth theory that meets the above kinds of knowledge-expectation conditions for its sentences. For this to be adequate, however, every true truth theory for a language that meets those conditions would have to assign to those expressions the same or equivalent semantic properties. Unfortunately this not true.

To see this let us return to the truth theory of our language *L*. As we saw in §2, it is possible to use that truth theory to derive a *T*-sentence for each sentence of *L*; and each such *T*-sentence plainly satisfies the relevant knowledge-expectation conditions. What is more, its axioms plausibly specify the meanings of each of *L*'s basic expressions. There are, however, other truth theories for *L* that meet the knowledge-expectation conditions for its sentences, but which do not specify the meanings of its basic expressions. For example, consider a truth theory for *L* which had the following axiom governing 'is red' instead of (3):

(6) 'is red' is true of something if and only if it is red and is either green or not green.

It would certainly be possible to derive all the correct meaning-indicating *T*-sentences for sentences of *L* on the basis of this axiom and the axioms governing the other basic expressions of the sentences. But (6) does not specify the meaning of 'is red' correctly.

It is true that we could rule out such cases by requiring that meaning-indicating *T*-sentences be proved in certain canonical ways - for instance, in the way we derived the *T*-sentence for 'Venus is red' in §2. For a proof that differed from that derivation only in using (6) instead of (3) would result in a *T*-sentence that did not satisfy the knowledge-expectation conditions, namely: 'Venus is red' is true if and only if Venus is red and is either green or not green. But this immediately raises the question why those ways should be thought of as canonical; and since the natural answer is that they ensure that the axioms governing the sentence's basic components specify their meanings correctly, it would seem that we must have some independent grip on what it is for those axioms to be so constrained as to have this property. The question is what provides us with that independent grip.

At this point, we may make a move analogous to the one made earlier in the case of sentences. There we noted that understanding the sentence 'Venus is red' involves knowing that it is true if and only if Venus is red, that speakers are expected to know this, and that this is the strongest thing speakers are expected to know about its truth-conditions. Similarly, we may say that understanding the predicate 'is red' involves knowing it is true of something if and only if that thing is red, that speakers are expected to know this, and that this is the strongest thing speakers are expected to know about the conditions under which it is true of something. (They will know, for example, that speakers will not be expected to know that it is true of something if and only if that thing is red and is either green or not green.) Equally, understanding the name 'Venus' will consist in knowing that it refers to Venus, that speakers are expected to know this, and that this is the strongest thing speakers are expected to know about what it refers to. Notice again that this solves our difficulty only for the very limited language *L*; but we may expect it to be soluble quite generally by means of similar kinds of knowledge-expectation conditions relating to whatever clauses govern other expressions and their modes of combination.

It should be noted that these kinds of knowledge-expectation conditions appear to put a considerable burden on the ordinary speaker: can we really picture them as part of the stock of knowledge possessed by speakers of a natural language such as English? At this point, if we are not to jettison the present approach, there seem to be three strategies. One is to claim that the truth-theoretic clauses are correct, to deny that we have knowledge of them (in the ordinary sense), but to insist that we bear some kind of analogous cognitive relation to them (yet to be fully explicated). The second is again to claim that they are correct, but to try to justify the ascription of tacit knowledge of them in some way. And the third is to see the truth-theoretic clauses as stepping stones to more convincing clauses which we can uncontroversially accept that we know.

4 Recalcitrant idioms and general difficulties

We turn next to a number of problems for the truth-conditional approach to meaning. In the light of Tarski's work, it is now clear how to accommodate within a truth-theoretic framework declarative sentences made up of names, predicates, truth-functors and standard quantifiers. But natural language seems much richer than this. We here consider two idioms which cause problems for the framework, and which in their different ways may require it to be modified. Then we consider two more general difficulties. It should be noted that there are various further issues - such as how the truth-conditional approach melds with doctrines of logical form, transformational grammar or validity - which, for reasons of space, we cannot discuss here.

Until now we have simplified matters by restricting ourselves to languages whose only sentences are declarative. This restriction is convenient, since - ignoring context-sensitivity - it means that all the sentences in the relevant languages have truth-conditions; but it is not warranted by natural languages, which contain sentences of many different moods, including imperatives, interrogatives and optatives. Such sentences do not appear to be truth-evaluable - 'Open the door, Smith!' or 'Where's the butter?' do not look like the kinds of sentence that can be true or false. Yet if they lack truth-conditions, it seems puzzling how they can be accommodated within a truth-theoretic framework.

One response is to add a further component to the semantic theory - what is sometimes called a theory of 'force' (see Pragmatics §8). This states what kind of speech act a given sentence is conventionally or typically geared to express; and it transforms the sentence into a corresponding declarative sentence which can then serve as input to the truth theory. For example, the theory of force for English would tell us that 'Open the door, Smith!' is a command, and that its corresponding declarative sentence is 'Smith opens the door'.

A second response is to introduce a number of further semantic values analogous to truth for each of the new types of sentence: compliance, for instance, for imperatives and optatives. Such values could be integrated into appropriate truth theories by means of such axioms as: *S*! is complied with iff *S* is true, where *S*! is the imperative form of a declarative sentence *S*. And to ensure that we obtain meaning-indicating compliance conditions, we could again use knowledge-expectation conditions, similar to those proposed in the case of declarative sentences, but with compliance replacing truth. Note, however, that both responses have great difficulty accommodating a sentence such as 'Open the door, Smith, and I'll put the kettle on' which contains more than one mood. Associated with this sentence, there seems no single speech act, nor any straightforward value analogous to truth.

Next we come to sentences whose truth-conditions can vary from one context to another. Such sentences, which

typically contain context-sensitive expressions such as personal pronouns, demonstratives, temporal and spatial indexicals, tense indicators and so on, evidently give rise to a problem for the programme of accounting for meaning in terms of truth-conditions. For although the truth-conditions of such sentences can vary from context to context, their meaning need not. The sentence ‘I helped that man yesterday’ means the same thing whoever utters it, whenever it is uttered and whoever the man is; but its truth-conditions will vary with the utterer, the time of utterance and the man indicated. Evidently, this is because in any ordinary way of taking the term ‘meaning’, the meanings of expressions such as ‘I’, ‘yesterday’ and so on are given by such general rules as that ‘I’ refers to the speaker, ‘yesterday’ refers to the day before the day of utterance and so on; but such meanings in themselves do not exhaust the contribution the expressions make to the truth-conditions of sentences containing them.

An amendment to the account is clearly needed. In particular, although we may take the truth-conditions of sentences to be identifiable with their meaning when they have context-free truth-conditions, we must identify those of context-sensitive sentences with a notion of content much stronger than ordinary meaning - roughly, with what the sentences express when the context has been fixed. This means that the semantic theory will in effect have to be divided into two parts: what supplies the context-free information relevant to truth-conditions; and what states the information about specific contexts that determines particular truth-conditions once the relevant context-free information has been supplied. The second part falls into the area of pragmatics (see Pragmatics; Demonstratives and indexicals).

Is this adequate? We here restrict ourselves to noting one general difficulty with the proposal. It is likely that most context-free semantic axioms will involve relativized semantic predicates. The pronoun ‘he’, for instance, might be governed by an axiom such as:

(7) For all *p*, *q*, the referent of ‘he’ as uttered by *p* to indicate $q = q$.

However, it is hard to obtain content-specifying instances of this which satisfy the appropriate knowledge-expectation conditions involving reference (see §3). For suppose I am the speaker and the person I am indicating is Quine. Then to display the content of ‘he’ in my mouth, we need a metalinguistic expression synonymous with it - ‘*a*’, say. This would give us:

The referent of ‘he’ as uttered by me to indicate Quine = *a*.

But even if we had such an expression, we would still face the problem that not all English speakers, even those in my immediate linguistic circle, need know of the referent of ‘he’ in my mouth that it is *a*. Indeed, I may be the only person who knows this. In such extreme circumstances, we could restrict the class of speakers to me. But it would then have to be the case that the strongest thing I expect myself to know about its referent is that it is *a*. And unfortunately there is no reason to think that this is so.

Finally we turn to two general problems for the programme of elucidating meaning in terms of truth-conditions, both of which have considerable contemporary significance. The first, antirealist difficulty focuses on sentences whose truth-conditions we cannot decide. According to one model of understanding, we can acquire and manifest an understanding of a sentence only if we can recognize whatever meaning-indicating condition is associated with it as obtaining when it does obtain and as not obtaining when it does not. But for sentences whose truth-conditions we cannot decide, the supposition that truth-conditions are meaning-indicating conflicts with this requirement. So in the absence of another model, the attempt to elucidate meaning in terms of truth-conditions must be jettisoned (see Intuitionistic logic and antirealism §6; Realism and antirealism §4).

The second difficulty concerns the definition of truth. It is clear that an extant notion of truth is needed to characterize meaning in the way we have been envisaging: we cannot use truth theories like the one described in §2 as analyses of truth, if only because they leave it unsaid how to apply the notion of truth to new languages. However, one of the most plausible independent accounts of truth, the ‘redundancy theory’ (see Truth, deflationary theories of), is arguably incompatible with any attempt to characterize meaning in terms of truth. For on one natural construal, this theory requires that understanding what it is for ‘Venus is red’ (say) to be true is tantamount to understanding what it is to say that Venus is red by using the sentence ‘Venus is red’. But to understand this, we already need to know the meaning of ‘Venus is red’.

Both objections seem to require that we replace truth by some other notion in an elucidation of meaning. One that

appeals to antirealists is that of warranted assertibility, since the conditions under which one would be warranted in asserting a sentence are arguably recognisable as obtaining when they obtain and as not obtaining when they do not. Other options would be to elucidate meaning in terms of communication intentions or conceptual role.

Meaning and understanding

The existence of a close connection between the notions of meaning and understanding can hardly be denied. I may be said to understand you, on a given occasion of utterance, when I know what you then meant - or, at least, when I know the meaning of the words that you then uttered. An important and influential school of thought within the philosophy of language goes much further than these platitudes, however. Its members adhere to the view that questions about meaning are essentially questions about understanding: 'a model of meaning is a model of understanding'. Their approach contrasts with that of those who expect an account of meaning to elucidate the nature of understanding only indirectly - perhaps by explaining meaning in terms of truth, inference, synonymy or self-expression, and only then explaining understanding as the correct recovery of meaning.

1 Dummett's account

The text of this article sketches and constrasts the views of the school's two leading members: Dummett and Davidson. The dictum 'a model of meaning is a model of understanding' was formulated by Michael Dummett. He proceeds to gloss 'a model of understanding' as 'a representation of what it is that is known when an individual knows the meaning' of a possible object of understanding - as it might be, a word, a construction, or a whole language (1973: 217). To provide such a model is to spell out the kind of knowledge that constitutes, or at least sustains, various kinds of linguistic understanding. Dummett's view is that the central philosophical debates about the nature of meaning are properly understood to be debates about the character of such knowledge. Slogans such as 'The meaning of a sentence is the method of its verification' or 'The meaning of a sentence consists in its truth-conditions' mean (if they mean anything at all) that to *understand* a sentence is to know how it may be verified or to know under what conditions it is true. In emphasizing that the central philosophical questions about meaning are questions about understanding, Dummett was self-consciously departing from a prior tradition (of which the most celebrated manifestation is Quine's 'Two Dogmas of Empiricism'); this tradition took the central problem in the area to be that of spelling out the conditions for two expressions to mean the same thing (see esp. Dummett 1981: 74).

Although Dummett canvasses various accounts of knowledge of meaning, it is a presupposition of his discussion that the knowledge in question is propositional. To attempt to produce a model of understanding is to attempt to produce a *theory*, knowledge of which constitutes or sustains possession of a linguistic capacity. In saying so much, Dummett is not committed to denying that an understanding of a word or sentence is in the first instance a matter of knowing how to use it. However, he is committed to denying that this formulation provides a complete account of understanding, he argues that we need a more detailed specification of what such know-how consists in (1973: 222-3). Dummett is also clear that the propositional knowledge in question will in general be implicit. That is to say, it is knowledge that a subject may possess even though he is unable to express the proposition thereby known. From this observation, Dummett derives a consequence that crucially constrains the sort of knowledge which he thinks might constitute or sustain understanding. 'Implicit knowledge', he says, 'cannot meaningfully be ascribed to somebody unless it is possible to say in what the manifestation of that knowledge consists: there must be an observable difference between the behaviour and capacities of someone who is said to have that knowledge and someone who is said to lack it' (1973: 217). In particular, then, the propositional knowledge, implicit possession of which is said to underlie understanding, must be manifestable in behaviour.

The significance of this requirement emerges when we consider the two models of understanding that Dummett centrally considers. Both of these models take to be central the problem of characterizing our understanding of declarative sentences, and according to the first of them - which Dummett labels a 'realist' or 'truth-conditional' model - such understanding 'consists in our grasp of [the sentence's] truth-conditions, which determinately either obtain or fail to obtain, but which cannot be recognized by us in all cases as obtaining whenever they do' (1972: 23). Thus, our understanding of the sentence 'A city will never be built at the North Pole' is taken by the realist to consist in our knowing that it is true just on condition that a city will never be built at the North Pole, a condition that may obtain without our ever knowing so (Dummett 1959: 16-7). This, Dummett argues, is rendered problematical by the requirement of manifestability. 'It is quite obscure', he writes, 'in what the knowledge of the condition under which a sentence is true can consist, when that condition is not one which is always capable of being recognized as obtaining' (1973: 224). The crucial claim, in other words, is that there is

something opaque about the attribution 'Tom knows that sentence *S* is true just on condition that a city will never be built at the North Pole'. Because the occasion may never arise on which somebody is granted the opportunity to give conclusive reasons for accepting the sentence as true or rejecting it as false, 'the knowledge which is being ascribed to one who is said to understand the sentence is knowledge which transcends the capacity to manifest that knowledge by the way the sentence is used'. Accordingly, the truth-conditional model of understanding cannot be one 'in which meaning is fully determined by use' (1973: 225).

Whether this really is a consequence of the truth-conditional model - and whether, if it is, it is sufficient to show that the realist model must be rejected - are questions that remain at the forefront of contemporary debate in the philosophy of language. As he made clear in 'Realism: A Valedictory Lecture' (1992), Dummett is not committed to particular answers. He has, however, articulated an alternative model of understanding which, whatever its other difficulties, is supposed to meet the requirement of manifestability. On this alternative 'antirealist' model, our understanding of a sentence will consist, not in knowing under what conditions it is true, but 'in knowing what recognizable circumstances determine it as true or as false' (1972: 23). Or, to deploy a formulation that Dummett treats as equivalent, it consists in knowing under what circumstances a sentence may be asserted. In addition to meeting the demand of manifestability, this model is supposed to have the merit of leading to a more plausible account of what learning a language involves:

> Thus we learn to assert '*P* and *Q*' when we can assert *P* and can assert *Q*; to assert '*P* or *Q*' when we can assert *P* or can assert *Q*…. We no longer explain the sense of a statement by stipulating its truth value in terms of the truth value of its constituents, but by stipulating when it may be asserted in terms of the conditions under which its constituents may be asserted.

> (1959: 17-18)

2 Davidson's account

It may seem as though Donald Davidson is a clear example of a Dummettian realist - someone who takes our understanding of a declarative sentence to consist in knowing the conditions under which it is true. However, while Davidson certainly regards the notion of a truth-condition as central to an account of a subject's linguistic competence, there are nuances in his treatment of these matters that make such a characterization misleading. He begins a celebrated article thus:

> Kurt utters the words 'Es regnet' and under the right conditions we know that he has said that it is raining. Having identified his utterance as intentional and linguistic, we are able to go on to interpret his words: we can say what his words, on that occasion, meant. What could we know that would enable us to do this? How could we come to know it? The first of these questions is not the same as the question what we *do* know that enables us to interpret the words of others. For there may easily be something we could know and don't, knowledge of which would suffice for interpretation, while on the other hand it is not altogether obvious that there is anything we actually know which plays an essential role in interpretation.
>
> (1973: 125)

Davidson is surely right to draw attention to the difference between his central question about knowledge of meaning ('What could we know that would enable us to know what these words mean?') and Dummett's ('What *do* we know when we know what words mean?'). But it is disappointing that he does not give his grounds for doubting that 'there is anything we actually know which plays an essential role in interpretation'. For if there is such actual knowledge, then questions about its character must surely be deemed more urgent and important than the hypothetical question that Davidson chooses to address. We appear, in other words, to need a reason for taking as central the problem upon which he focuses.

Be that as it may, Davidson's own question is a clear one, and his writings contain two rather different answers to it. In his early papers (roughly speaking, those published before 1970, including the influential 'Truth and Meaning' of 1967), we are told that what would suffice for interpreting a speaker *A* at time *t* is knowledge of a truth theory that is interpretative for *A* at *t*. A truth theory, as Davidson conceives it, comprises statements (*T*-theorems) to the effect that a sentence is true (as potentially uttered by such-and-such a speaker at this or that time) just in case a certain condition is met. And such a theory will be interpretative, for a speaker at a time, if (intuitively) the condition that the theory associates with each sentence gives the meaning that it then has in that

speaker's mouth. Plainly, this answer is of little interest without some independent specification of the condition for a theory to be interpretative (independent of the notion of meaning), which Davidson hopes to provide via the figure of the radical interpreter. Such an interpreter is an investigator who constructs a truth theory for a speaker (at a particular time) in accordance with certain general interpretative maxims or constraints, chief among which is the principle of charity (see Davidson 1973; Lewis 1974; Charity, principle of §4; Radical translation and radical interpretation §7-10). The idea, then, is that it is such maxims as these that give content to the requirement that a theory be interpretative, and thereby give content to the notion of meaning.

The model of understanding and meaning that results involves a substantial holism. The condition for a sentence *S* to mean that *p* as a speaker *A* uses it at time *t*, is that a truth theory that is interpretative for *A* at *t* (that is, a truth theory that optimally meets the constraints under which the radical interpreter operates) should contain among its *T*-theorems the result '*S* is true (as potentially uttered by *A* at *t*) just in case *p*'. This makes it clear that the condition for a sentence to have a certain meaning involves reference, not just to the components of *S*, but to the totality of sentences that the relevant speaker is then disposed to utter (see Davidson 1976: 175). This holism does not alarm Davidson, but he has confessed to an important error in his earlier answer to his question. 'My mistake', he wrote in 1976, 'was to overlook the fact that someone might know a sufficiently unique theory [that is a theory that optimally satisfies such constraints as the principle of charity] without knowing that it was sufficiently unique' (1976: 173). He duly amends his account of what suffices for interpretation to correct this mistake: 'what somebody needs to know [in order to interpret speakers of a language *L*] is that some [sufficiently unique] *T*-theory for *L* states that… (and here the dots are to be replaced by a *T*-theory)' (1976: 174).

The occurrence in this formulation of the intentional and linguistic verb 'to state' may lead one to wonder whether the account is invoking a notion to which it is not entitled (compare Forster 1976). After all, if we are allowed to use a verb like 'state' in specifying the knowledge that would suffice for understanding, then why should we not bypass the complexities of truth theories completely, and say simply that what suffices for interpreting a speaker is knowing what he would be stating by affirming declarative sentences, what he would be asking by uttering interrogative ones, and what he would be ordering by uttering imperative sentences? Davidson, however, has a convincing answer to this question. Although the use of the verb 'state' (or, as he eventually prefers, 'entail') 'brings in an appeal to a specifically linguistic notion', it is a notion that has been 'elicit[ed] by placing conditions on a theory of truth' (1976: 178). That is to say, its content must be understood in relation to the conditions for a truth theory to be interpretative.

All the same, one might wonder whether a more direct method of eliciting (or explaining) such a notion was not available. Instead of considering truth theories - and regarding the principle of charity and its ilk as providing conditions for a truth theory to be interpretative - why should we not consider theories entailing such claims as that:

By affirming *S* at *t*, *A* would state that *p*

and regard the relevant principles as conditions for such a theory to be *true*? Davidson's answer appears to be that certain logical difficulties arise in the latter case that are absent from the former. In an early paper, Davidson wrote that 'when we can regard the meaning of each sentence as a function of a finite number of features of the sentence, we have an insight not only into what there is to be learned; we also understand how an infinite aptitude can be encompassed by finite accomplishments' (1965: 8). The context makes it clear that the present occurrence of 'when' means 'when and only when' and the suggestion is that such insight will be gained only when we have an axiomatization - if not finite, then at least recursive - of the body of knowledge in question. Now Davidson also suggests that a theory whose theorems are in the form:

By affirming *S* at *t*, *A* would state that *p*

will resist axiomatization. 'It is reasonable to expect', he writes, 'that in wrestling with the logic of the apparently non-extensional "means that" [and, we might add, the equally non-extensional "would state that"] we will encounter problems as hard as, or perhaps identical with, the problems our theory is out to solve' (1967: 22).

But are such problems insuperable? Surely one can account for somebody's knowing that Kurt uses 'Es regnet und es schneit' to state that it is raining and snowing by reference to his knowing:

(1) that Kurt uses ‘Es regnet’ to state that it is raining
(2) that Kurt uses ‘Es schneit’ to state that it is snowing

and

(3) that (*p*)(*q*)(*S*)(*S′*)(If Kurt uses *S* to state that *p*, and uses *S′* to state that *q*, then he uses ‘*S* und *S′*’ to state that *p* and *q*)?

One source of concern about this last item of knowledge may be that the initial pair of quantifiers must be understood substitutionally (see Quantifiers, substitutional and objectual), but it is noteworthy that on Davidson’s preferred analysis of such constructions as ‘states that’, there is a far more acute problem. On his ‘paratactic’ analysis, what follows the word ‘that’ in an attribution such as ‘Galileo stated that the earth moves’ belongs in a semantically separate sentence from the properly attributive claim ‘Galileo said that’ (see Davidson, D. §6; Propositional attitude statements §3). Applied to (c), then, the substitutional quantifiers ‘(*p*)’ and ‘(*q*)’ would reach into a different sentence. Here, the ‘direct’ approach to theories of meaning seems to take us into uncharted logical waters. Unless Davidson’s analysis of indirect discourse can be shown to be wrong, or unless some way can be discovered of charting these waters, we have a reason for answering his question in the way that he recommends.

Meaning and verification

The verifiability theory of meaning says that meaning is evidence. It is anticipated in, for example, Hume's empiricist doctrine of impressions and ideas, but it emerges into full notoriety in twentieth-century logical positivism. The positivists used the theory in a critique of metaphysics to show that the problems of philosophy, such as the problem of the external world and the problem of other minds, are not real problems at all but only pseudoproblems. Their publicists used the doctrine to argue that religion, ethics and fiction are meaningless, which is how verificationism became notorious among the general public.

Seminal criticism of verification from around 1950 argues that no division between sense and nonsense coincides tidily with a division between science and metaphysics, as the positivists had claimed. Quine later developed verificationism into a sort of semantic holism in which metaphysics is continuous with science. In contrast, Dummett argues from a reading of Wittgenstein's claim that meaning is use to a rejection of any sort of truth surpassing the possibility of knowledge, and thence to a defence of intuitionistic logic. But the claim that all truths can be known yields in an otherwise innocuous setting the preposterous consequence that all truths actually are known. There are ways to tinker with the setting so as to avoid this consequence, but it is best to conclude by reductio *that some truths cannot be known and that verificationism is false. That in turn seems to show that the prospects for an empiricist theory of meaning are dim, which might well shake a complacent confidence in meaning.*

1 Hume

Perception is the only channel to us from the world whose influx is generally accepted to justify our beliefs about the world. Beliefs figure as units of justification in this empiricist-sounding doctrine. Since justifying something is giving a reason for thinking it true, the units of justification should be the right size for being true or false. Word-sized bits, be they words themselves or their meanings or people's ideas of things, are too small, while paragraph-sized chunks are too big, but sentence-sized stretches are of just the right size and unity for having truth-values. It is natural to take the things believed and justified by experience to be sentence-sized or propositional.

But the unit of Hume's seminal empiricism seems smaller. He begins the *Treatise of Human Nature* (1739-40) with the doctrine that all ideas are derived from impressions. To the extent that Hume made a self-conscious distinction between words and sentences (on the language side), or between concepts and propositions (on the Platonic side), or between ideas and thoughts (on the psychological side), the ideas Hume had in mind seem smaller than sentence-sized. In that way, Hume's empiricism seems narrower than the doctrine with which we began.

Hume claimed ideas are derived from impressions by copying, the copies differing from their originals only in vivacity. Ideas and impressions were thus to be images, the ideas merely fainter reproductions of the impressions. Objections to taking abstract ideas as images predate Hume, but the doctrine at least places ideas in a familiar psychological category. Items in this category are accessible to inner sense or introspection if anything is, and thus are knowable by processes such as those of the five outer senses already empirically certified. Admittedly, images seem too particular to reflect the abstract nature of abstract ideas. But at least acquaintance with images could explain action. If we try to rethink ideas not as images but as capacities or dispositions, we seem left with bare possibilities or potentialities, ungrounded in actualities which could explain action. Faced with a choice between bad theory and none, we often seem to prefer the bad to none; at least bad theory may provide a (risky) basis for getting on, but none provides none. Thinking of ideas on the model of images does not go away.

The doctrine that ideas are images derived from sense impressions by copying can be put to work in two different ways. One might take it for granted that we do indeed have certain ideas we seem to have, and then cast about for impressions from which such ideas might be derived; such a cast might well hook surprisingly unfamiliar epistemic fish. Alternatively, one might start from a catalogue of familiar impressions, and then winnow out ideas that cannot be derived by copying any such impressions; such a purge might well leave a rather sceptical residue.

Hume thought of himself as a sceptic. Causation and the self are two examples of this sceptical pattern in Hume. In

the case of causation, he never seems to have said exactly which impressions are wanting. Kant writes that experience teaches us that a thing is so-and-so, but not that it cannot be otherwise (*Critique of Pure Reason*, 1787: B3). In Hume's terms, we have impressions only of actuality, never of necessity; we see red, but not having-to-be red. But then there is no impression of necessity from which to derive an idea of it, so there is no making sense of causation as necessitation. At most we experience regular succession (with temporal priority and spatial contiguity), so that is all there can be to our idea of causation. Thus Hume's scepticism about necessary connection in nature is linked to his doctrine of ideas. In the case of the self, Hume asserts quite explicitly that there simply is no such thing as an experience of oneself over and above the ideas and impressions revealed to introspection. So, he infers, there can be nothing to the self and our idea of it but the bundle of the contents of consciousness. This bundle theory of the self has always seemed one of the more shockingly sceptical parts of the *Treatise*.

2 Logical positivism

We have now seen how Hume can use his doctrine of impressions and ideas as a sceptical weapon. The Vienna Circle between the two world wars of the twentieth century claimed an intellectual lineage back to Hume, and it is the Circle to whom we credit (or on whom we blame) the verifiability theory of meaning (see Vienna Circle §3). It would be an anachronism to attribute to Hume our preoccupations with language, meaning and reference. But imagine a philosopher already so preoccupied reconsidering Hume's doctrine of impressions and ideas. Many find it difficult to become accustomed to a self-conscious distinction between the meaning of an expression and what a person means by that expression. Without such a distinction at one's fingertips, it is all too easy to slide between the meaning of an expression and the ideas expressed by people using that expression. If our philosopher also admires Hume's empiricism, they may incline towards the doctrine that these ideas must be derived from impressions. The core of empiricism is the view that sense experience is the basic sort of evidence we have for (that is, for verifying) our beliefs about the world. It is then not unnatural for this suspension - of meaning, ideas, impressions and verification - to precipitate out a verifiability theory of meaning, or at least the slogan that meaning is evidence.

The verifiability theory of meaning may not be present in the greatest works of Vienna positivism, such as Carnap's *Aufbau* or his *Logical Syntax of Language* (see Carnap, R. §§1-3). But it does seem to animate his *Scheinprobleme in der Philosophie* (*Pseudoproblems in Philosophy*, 1967) and it is obvious in Ayer's *Language, Truth and Logic* (1936), an enormously noticed popularization of logical positivism (see Ayer, A.J. §§2-3). In so far as the positivists had verificationism, they used it as a weapon of criticism. Hume's scepticism can be taken as criticism of complacent confidence in causes and the self, but it would be a distortion to assimilate verificationist criticism without further ado to Hume's scepticism. On the contrary, Carnap's *Pseudoproblems* shows him using verificationism to criticize certain sceptical lines of thought, the problem of the external world and the problem of other minds.

Descartes (1641) denied the pretensions of sense experience to be utterly basic to knowledge and its justification. To that end, he asks how one knows one is not asleep and dreaming right now. Come to that, perhaps one has been asleep and dreaming all of one's life, and all one's experience, instead of reporting the world of matter it seems to present, is instead merely an interminable hallucination spun by oneself out of whole cloth. This difficulty is the problem of the external world (see Descartes, R. §9). Indeed, perhaps there is no matter at all, but only one's mind and the endless illusions one foists on oneself. Here we have two incompatible hypotheses. One says that there is the matter out there independent of us that there seems to be, subject to the laws of nature. The other says that there is no such matter, but only the hallucination of it one foists on oneself. It is crucial to Descartes' case that the sense experience forecast by these two hypotheses be indistinguishable. For we are to be sure that the matter hypothesis is true and the dreaming hypothesis is false, and since sense experience cannot separate the two, there must be some other way of knowing, perhaps even more basic than experience, since it is what entitles us to take our experience to support the matter hypothesis. Prominent along that way are the *Cogito* and the ontological proof of the existence of God. Many after Descartes are not persuaded that his way leads anywhere. So they are left without an answer to how they know they are not asleep and dreaming.

In the way one feels one's own headache and observes its location, extent and intensity, there is nothing remotely like feeling someone else's pain or apprehending another's experience. Still less can one see or hear or smell or touch or taste another's experience and come to know it in that way as they do. But then for an empiricist there

arises the question of how one knows anyone else even *has* experience and feeling. Why could all one's own experience not be just as it has been and yet all the other human bodies be mindless lumps (acting as if someone with thoughts and feelings and experiences were in there but really) driven only by blind chemical reactions? This is the problem of other minds, and does not seem to go back earlier than John Stuart Mill in the nineteenth century. Mill offered an argument from analogy to solve this problem. One knows first hand from one's own case that it is one's headache that makes one wince just so, and seeing a similar wince on another's face, one infers by analogy a similar cause, namely a headache, in that other. This argument from analogy proceeded from what must be a single case, namely, oneself alone, so can it justify much certainty? Beyond that, the argument seems not even to address the difficulty the problem of other minds may raise for empiricism, namely, how one could know things like another's pain which one simply could not experience.

3 Logical positivism (cont.)

One can make out connections between Hume's doctrine of ideas and the verifiability theory of meaning, but while Hume used his doctrine as a sceptical axe, the positivists used their story of meaning to undercut scepticism. The problems of the external world and of other minds came to figure centrally on the agenda of modern classical philosophy. Philosophical problems rarely if ever receive solutions consensually certified, so it is understandable (even if not quite right) that such problems apparently sit there forever unsolved. In that case, these problems can easily come to look like demonstrations that it is not known whether there is any matter out there and that it is not known whether there is anyone besides oneself. In that way the agenda of modern philosophy can seem to be a compendium of sceptical theses. But the verifiability theory of meaning was used to argue that these so-called problems are not problems deserving solutions, but pseudoproblems deserving only dissolution. If one asks of a bachelor whether his wife is English, both a yes and a no seem bad answers since both seem to confirm a mistake concealed in the question. This trite example is a very simple illustration of how a misconception can present itself as an insoluble problem. Some of what is or was modernist in philosophy was an idea of criticism not as demonstrating the opposite but rather as unmasking, and thus eliminating, fraudulent questions and problems.

How was this to work? Remember that Descartes designed the dreaming hypothesis with the intention that it and the matter hypothesis issue in exactly the same expectations for sense experience; everything would seem the same to one's senses no matter which of the two were true. So by design no sensory experience could settle the question of which is true; both hypotheses are equally well supported by all perceptual evidence. But on the verifiability theory, meaning is evidence. As the old slogan had it, a difference that makes no difference is no difference: claims that cannot be distinguished on the basis of evidence must coincide. So since no sensory experience could discriminate between the matter and the dreaming hypotheses, and since empiricism is right, and sensory experience is the only evidence against which to judge claims about the world, then the two hypotheses have exactly the same evidence, and so, by verificationism, exactly the same meaning. Since they are synonymous, they are not incompatible at all, but as compatible as possible. Hence, there is no question at all of choosing between them, and so, since that question is what the problem of the external world was, there is no such problem. The problem has been dissolved.

In the case of the problem of other minds, it is granted that all we can observe of other people is their physical behaviour (and, for an audience some sixty or seventy years later, electrochemistry in their central nervous systems). The problem is whether they really have minds and thoughts, or are just mindless chemical machines. But it is granted that both these alternatives would issue in exactly the same observations of others, and, by empiricism, such observation exhausts the evidence for either. Hence, the alternatives do not differ in evidence and so do not differ at all. There is thus no choice between them, and so no problem of other minds.

Perhaps the truly devout will hang on to their faith no matter what. In that case it looks as though nothing could count against it. Equally, no experience really counts as evidence for faith. But if faith is free from sensory evidence, then, since by verificationism meaning *is* evidence, religion is meaningless. It was not an accident that believers found such irreligion (and affronts to ethics and poetry as well) in Ayer's potboiler, *Language, Truth and Logic*. (One thing that is distressing here is that some thought they could defend their faith only by showing it empirically verifiable rather than by rebutting verificationism. The devil has no right to pick the battlefield.)

4 Objections to verificationism

One sort of objection to verificationism begins with the observation that evidence for a present claim about ancient events will be contemporary with the claim rather than with the events. Then the claim about the past seems paradoxically to be about the present, and this paradox seems to be an objection to verificationism. But the objection seems to be founded in a confusion between the date of a report and the date, if any, mentioned by the report. It may be mysterious how words, simultaneous with their present meanings, can reach across time to refer to things past (see Proper names §4). But we have yet to be shown how, if present meaning is present evidence, that mystery is any deeper. Yet if present evidence must be present experience, and experience can only be experience of what is (pretty much) contemporary with it, then the objection may be more forceful. (The finiteness of the speed of light means we can see novae long past, but we cannot choose the temporal distance at which we see while we can choose that at which we refer.)

A monument in the criticism of verificationism is Carl G. Hempel's 'Problems and Changes in the Empiricist Criterion of Meaning' (1950). Let us ask in seeming innocence exactly what the verifiability theory of meaning is. It is natural to put the theory by saying that the meaning of a (declarative) sentence is the body of sensory experience that would conclusively establish the sentence; here verification is required to be knock-down. To this form of the theory, Hempel presents three objections. First, natural science, the positivists' paradigm of meaningfulness, is full of universal hypotheses, though, as the problem of induction shows, no genuinely possible body of evidence ever suffices to establish a universal claim conclusively. Second, suppose that *S* typifies what the positivists count as meaningful while *N* typifies what they count as meaningless nonsense. Note that the disjunction, *S* or *N*, follows from *S*; yet if a part is gibberish, one expects the whole to be so too - how can nonsense follow from sense? Third, let *P* be a feature one can observe an object to exhibit or to lack. One observation would suffice to establish conclusively that there is a thing with feature *P*. But then the sentence 'There is something with *P'* is meaningful, while its negation, being universal, is not, though it seems unbelievable that a sentence be meaningful, while its negation is not. These three arguments are not meant to be decisive. Instead they represent a turn in the dialectic both of Hempel's 1950 paper and of verificationism. But through the 1950s and into the 1960s, there was a rather general presumption that verificationism was dead, and that Hempel's paper was its headstone (see Logical positivism §5).

5 Recent developments

But ideas are hardy. After Hume, the gap between experience and theory grows. Perhaps statements which are just about experience can be tested one by one against experience, but the more theoretical a statement, the less it can be so tested individually. Around 1900 Pierre Duhem argued that theoretical statements can be tested against observation only in relatively large, heterogeneous bodies (see Duhem 1906; Duhem, P.M.M. §4). Half a century later, Quine (1961) inferred from verificationism that the smallest unit with meaning is the smallest unit to which empirical evidence attaches. By Duhem's thesis, such units of evidence are large and heterogeneous in the case of theoretical sentences (see Quine, W.V. §3). But that is the more general case, and in it we cannot distinguish different meanings for different sentences; as it were, mostly there are no propositions. In particular, meanings for the mathematics used in theoretical science cannot be distinguished from meanings for the natural laws used there. Thus we lose all basis for saying such mathematics is true by virtue of its meaning (analytic), while those laws are not certified by their meanings alone. Quine thus uses one central tenet of positivism (verificationism) to undercut another (the analyticity of mathematics - see Analyticity §3). This reopens a path to Platonic metaphysics in mathematics, a path positivism thought to block.

Quine develops verificationism towards a semantic holism rather alien from positivism (see Holism: mental and semantic). But from around 1970 Michael Dummett (1975), taking a cue from the later Wittgenstein (§14), revives a verificationism more reminiscent of positivism. The later Wittgenstein sometimes seems to flirt with intuitionism in the philosophy of mathematics. The strictures intuitionism would impose on classical logic hardly seem obvious. But Dummett suggests that those strictures may fall out of a proper theory of meaning (see Intuitionistic logic and antirealism §§4-6). Meaning, Wittgenstein said, is use, and use, Dummett says, is public; the upshot is what Dummett calls the extrusion of meaning (from, perhaps, the mind into, perhaps, public life). Sometimes he presents this extrusion as the proper response to two challenges, one of acquisition, another of manifestation. The point of the first is that no matter what ideas are innate, a child learning its mother tongue has only observations of which words those around it use in which circumstances on which to base its expressions of its ideas. Meaning must be publicly observable to be learned by speakers (see Private states and language). These challenges are

challenges to an account of meaning in terms of truth-conditions, an account of meaning that may have been present in Frege (1884) and that is explicit in Donald Davidson (1984). The idea here is that the meaning of a sentence is given by the conditions for its truth (see Meaning and truth §1). Taken standardly, there is no guarantee that we can tell of what is true that it is true; Dummett describes such truth as ‘verification transcendent’. If the truth-conditions which constitute meaning transcend recognition, then it would seem there is no guarantee that meaning will be manifest enough to be acquired by native speakers. So, since meaning must be knowable for communication to be possible, verification-transcendent truth must be an illusion. But truth so conceived is crucial to the exposition of classical logic; when we say that a statement or its negation is always true, we mean to allow that neither need be known. If we treat from conditions of truth to those of assertibility, as Dummett thinks we must, the logic we get is, he argues, that of intuitionism.

6 Logical problems

It is a consequence of the rejection of verification-transcendent truth that all truths can be known. This may also be a consequence of verificationism itself: any truth is meaningful and so, by verificationism, has attached to it evidence that can be had, thus making the truth known. Dummett is quite clear about the commitment that all truths can be known. Here it seems important to separate possibility from knowledge. There is, presumably, a natural number *n* such that Caesar had exactly *n* hairs on his head at the instant Brutus’s dagger first penetrated Caesar’s body. To say that it can be known that Caesar then had *n* hairs may be true, while it is pretty clearly false that it is in fact known; the possibility of knowledge should allow for the fact of ignorance.

Take a system for the propositional calculus. Add to it a very weak modal logic in which necessary conditionals with necessary antecedents have necessary consequents (Gödel’s axiom) and in which necessitations of theorems are also theorems; the latter is OK if all our axioms are necessary and all our other rules of inference preserve necessity. This weak modal logic is all we need about necessity and possibility on their own. As for knowledge, we make three postulates. A1 says that all truths can be known. This can be written ‘If *p* then it is possible that (‘$\Diamond$’) it is known that *p*’,

$$p \rightarrow \Diamond \mathrm{Kp}.$$

A2 says that what is known is true. This can be written

$$\mathrm{K}p \rightarrow p.$$

A3 says that when a conjunction is known so are its conjuncts. This can be written

$$\mathrm{K}(p \mathbin{\&} q) \rightarrow (\mathrm{Kp} \mathbin{\&} \mathrm{Kq}).$$

A2 is part of all stories of knowledge, and as for A3, it is hard to see how an explicit conjunction could be known without being understood, and so its conjuncts known. Call the whole system *F*. In *F*, we can prove that all truths are known; this can be written

$$p \rightarrow \mathrm{Kp}.$$

Here is how the proof goes. Suppose that *p* but that it is not known that *p*; suppose, in short, that $p \mathbin{\&} {\sim}\mathrm{Kp}$. By A1, $\Diamond \mathrm{K}(p \mathbin{\&} {\sim}\mathrm{Kp})$. A3 says K distributes across conjunction, and weak though our modal logic is, it is strong enough to make the distribution inside the diamond. So $\Diamond(\mathrm{Kp} \mathbin{\&} \mathrm{K}({\sim}\mathrm{Kp}))$. A2 says the outermost K of the second conjunct can be dropped, and weak though our modal logic is, it is strong enough to drop this K inside the diamond. So $\Diamond(\mathrm{Kp} \mathbin{\&} {\sim}\mathrm{Kp})$. This says an explicit contradiction could be true, a possibility refutable even in our weak modal logic. So our original supposition that $p \mathbin{\&} {\sim}\mathrm{Kp}$ has been reduced to absurdity, and thus we have shown that $p \rightarrow \mathrm{Kp}$. (This argument has a curious provenance. It was published by Fitch in 1964, but Fitch attributes it to the anonymous referee of a paper he submitted, but did not publish, in 1945.)

General omniscience is utterly preposterous. If nothing else, it would collapse the distinction between knowledge and truth, leaving nothing to discover. If not all truths are known, then at least one of the postulates of *F* must be mistaken. Faulting the propositional calculus here seems excessive - like using cannon to hunt sparrows. If one is willing to countenance modality at all, then Gödel’s axiom seems acceptable. Whether the rule of necessitation RN is acceptable depends on whether the axioms of *F* are necessary and the other rules preserve necessity. It is

generally held by those who take necessity seriously that the laws of the propositional calculus are necessary and that, say, *modus ponens* preserves necessity. Gödel's axiom too is generally thought necessary by the friends of modality. That leaves only our axioms A1-A3 of knowledge. A2 says that only truths are known; this claim is generally held to be analytic and thus necessarily true. A3 says that the conjuncts of a known conjunction are known. This claim follows, for example, from the more general claim that the logical consequences of what is known are also known. The more general claim is usually rejected since, for example, one seems to be able to know the axioms of number theory but not to know all its theorems. Nevertheless, it is only A3 and not the more general claim that is at issue here. It is at least difficult to imagine how an explicit conjunction might be known, and hence understood, unless its conjuncts also were known. If so, A3 is necessarily true and, thus, true. That leaves only A1, the focus of our original interest. If A1 is not true, then neither is it necessarily true, in which case RN is not to be trusted in *F*. Quite independently of *F*, there is a suspicious hubris in A1. What would give sentient beings the arrogance to suppose themselves so smart as to be able to figure out everything? Perhaps good manners as well as good judgment urge the denial of A1.

Still, one might feel as if a trick were being played on one; can just this dinky little logic chopping really be all it takes to show there absolutely must be ignorance? This seems like too much out of too little to be believed. So one might think that maybe there is a blunder somewhere, and one thing in the argument that bothers some people is the way it nests K inside itself. So one might consider typing (assigning 'levels' or 'types' to) knowledge, rather as Russell (1908) typed classes, or Tarski (1933) levelled languages. It is by no means obvious how to distinguish types, but custom suggests treating them like numbers. Then we would have not a single K, but rather an infinity K_1, K_2 and so on *ad infinitum*. Aping Russell, our syntax might insist that $\mathrm{K_n}$ be applicable to a formula *p* only if, when there are operators $\mathrm{K_m}$ in *p*, *n* is the successor of the largest such *m*. A2 and A3 could be postulated for each such operator uniformly. The novelty would crop up in A1 to block the first step in the proof that $p \rightarrow \mathrm{K_n p}$. Moreover, as Hans Kamp and Charles Parsons showed independently, the result is a consistent system in which $p \rightarrow \mathrm{K_n p}$ fails.

This result depends on sealing off the positions in which types are mentioned from quantification. For otherwise we could re-introduce K so that K*p* means that $(\exists n)\mathrm{K_n p}$, and in this way recover the old proof that $p \rightarrow \mathrm{Kp}$. We are thus landed in an indefinitely extended realm of types (or levels or contexts) that we have to be able to distinguish and mention. Presumably we could introduce a predicate true of all and only the types. This makes it seem like mere artifice or arbitrary convention (like not using one's hands in soccer) not to allow quantification over types. We cannot even say that knowledge is always of some type. In other words, typing without quantification is more like hiding the paradox than solving it. There is nothing special here about knowledge, for types without quantification also seem equally unsatisfactory solutions to the set-theoretic and semantic paradoxes.

Typing is not the only way one might try to diagnose trickery in *F*. A more radical move would be to take our results about *F* as a refutation of A1, as a proof that not all truths can be known and so as a refutation of the verifiability theory of meaning. What might the falsity of verificationism tell us about meaning? Verificationism would fail if there were differences in meaning which no differences in evidence - and thus, granted empiricism, sensory evidence - answered. That would in turn happen were there two sentences that differed in meaning, which would be most convincing if they could or did differ in truth-value, but such that there would be no possible way to tell by looking, listening or otherwise observing, which is true. Here we have reached a description of Descartes' problem of the external world. The matter hypothesis says that there is matter, while the dreaming hypothesis does not. On the very face of it, the two hypotheses are incompatible, and so not synonymous. If a language is to be usable for communication among its speakers, then they must know what its expressions mean. In general, when two of its expressions seem non-synonymous to its speakers, they will be non-synonymous. The dreaming and matter hypotheses seem non-synonymous to us. So if the verifiability theory of meaning says they are synonymous, then so much the worse for verificationism. As a response to the problem of the external world, verificationism was whistling in the dark.

Differences in meaning are not guaranteed to be rooted in sensory differences. Put otherwise, in a more archaic vocabulary, ideas are not images; nor are they faint copies of impressions. This is hardly hot news, and yet it raises in an acute way a worry about whether an empirically acceptable account of what meaning is can be had. What kind of a thing is a meaning? How can that be a difficult question given that since you and I know a natural language, we are both familiar with lots of meanings?

Meaning in Islamic philosophy

The discussion of the notion of meaning in Islamic philosophy is heavily influenced by theological and legal debates about the interpretation of Islam, and about who has the right to pronounce on interpretation. The introduction of Greek philosophy into the Islamic world produced a new set of authorities on how to interpret texts, and this led to arguments over the potential benefits of the new approaches as compared with the traditional Islamic sciences. The discussion came to centre on the nature of ambiguity, equivocation and analogy, with different philosophers adopting diverse theories and thus attaining a variety of conclusions about how to interpret meaning. These variations have powerful implications for the understanding of their thought. Not only do the different approaches result in different conclusions, they also represent different approaches to the whole philosophical enterprise. The topic of meaning is not so much an aspect of Islamic philosophy as an interpretation of how to do Islamic philosophy itself. The main issues focus on identifying the people best qualified to interpret texts, valid interpretations of the texts, and the notion of meaning that should be employed in our understanding of the texts.

1 Religious context

Since the Qur'an was transmitted in Arabic, an understanding of the nature of that language is a vital aspect to an understanding of the text itself. Those brought up within the traditions of jurisprudence, grammar and theology were of the opinion that they were the best positioned to pronounce on the meaning of the text (see Islamic theology §1). All scriptures require interpretation, and a wide diversity of views arose within the Islamic community over the correct reading of much of the Qur'an, with the creation of different schools of thought based upon political and religious divisions such as those between the Sunni and the Shiʿi communities and between the Ashʿarites and the Muʿtazilites (see Ashʿariyya and Muʿtazila §1). It was accepted quite early on that while some parts of the Qur'an are clear, others are less easy to grasp and so require more complex interpretations. Some passages are *zahir* (exoteric) while others are *batin* (esoteric), and naturally the commentators disagreed on occasion over which texts fell into which category and how the esoteric texts were to be read. In a religious text, of course, even the apparently plain and commonplace can be given a richer and deeper interpretation, and different interpreters produced different interpretations. None of these was arbitrary. All were based upon argument and a variety of Islamic sources, but this hermeneutic process was capable of arriving at a variety of conclusions.

2 Language versus logic

The arrival of Greek logic in the Islamic world caused great controversy in the fourth century AH/tenth century AD. It brought with it the view that logic is superior to language since the latter deals only with the contingent and conventional, while logic encompasses the necessary and the universal. Language deals only with *alfaz* (utterances), while logic gets to the heart of the matter by analysing *maʿani* (concepts) themselves. This controversy was explored in the celebrated debate between the grammarian Abu Saʿid al-Sirafi and the logician Abu Bishr Matta in Baghdad in AH 320/AD 932. Matta argued that logic was more important than language since the meanings which are embedded in a particular language are analysable without reference to that particular language. Those meanings could exist in a whole variety of languages. Logic is the only rigorous tool for judging when language is used correctly or otherwise, and the logician is the best qualified to adjudicate on such issues.

This was a very important debate, since if Matta were to carry the day it would imply that the traditional approach to Islamic texts rests on an error. Only logic, as understood by the Greeks and a non-Muslim such as Matta, is a sound vehicle for the understanding of texts. Al-Sirafi was clear on the significance of the debate, and he argued that it is impossible to separate language and logic in the way Matta wants. Although logic is useful at one level in dealing with concepts, it is far from comprehensive and is better suited to analysing the Greek language than the Arabic. Problems in understanding Arabic texts can only be answered by a good understanding of the Arabic language and the culture which surrounds it. Logic by itself is not sufficient (see Logic in Islamic philosophy).

This sort of debate continued in the Islamic world for some time, albeit in a more sophisticated form. The debate is highly significant, since it is really about the appropriate notion of meaning to be employed. Must that notion of meaning be taken from the context in which the text to be analysed has itself originated, or can it come from elsewhere? How one answers this question has radical implications for the way in which Islamic philosophy is to

be pursued, and the protagonists of the argument are well aware of this.

3 Ambiguity, equivocation and analogy

There are two main theories of meaning in Islamic philosophy, one broadly Neoplatonic and adopted by Ibn Sina (Avicenna) and al-Ghazali, and one broadly Aristotelian and defended by Ibn Rushd (Averroes). On the former account, the definition of *x* does not include the existence of *x*, so that something else is required to move *x* from the realm of possibility to the realm of actuality if it is to be instantiated. For Ibn Sina the mover is another thing, ultimately God, which causally necessitates the change, while for al-Ghazali it is God who directly established quite arbitrary rules for the behaviour of contingent phenomena. This means that for al-Ghazali it is possible to think of something happening without its customary explanation, that is, without a natural explanation. God could always have brought it about that people on occasion write philosophy books without possessing a head, or that straw does not burn when in contact with fire.

Ibn Rushd operates with a different concept of meaning, in accordance with which the cause of an event is part of its definition or essence. If headless people were to start composing philosophical books we should need to construct an entirely novel conceptual scheme for such a possibility to make sense. Al-Ghazali, by contrast, argues that we can conceive of such changes to our conceptual scheme by using our imagination, and failure to approve the possibility of such changes is merely a result of intellectual laziness, not the flouting of necessity. It is possible, then, for God to do anything he wishes so long as it is logically possible. God can resurrect the dead, he can intervene in the natural world, he can be aware of events in the world, he can create that world at any time he wishes out of nothing. These are all actions which Ibn Rushd argued are not possible even for God, if what is meant when talking about such actions is similar to what we mean when we talk about what we do. Al-Ghazali suggests that any analysis of the properties of God which interprets them as equivocal, ambiguous or metaphorical is a subtle attack upon the notion of God in its religious sense. It involves pretending to make God part of one’s metaphysics but changing the way in which one talks about him to such an extent that he no longer is equivalent to the God of Islam.

For Ibn Rushd, there are serious problems in talking about God using the same sort of language we use about ourselves. God cannot be defined in terms of a genus or species since he cannot consist of a plurality of qualities as we do. Rather, he is the exemplar of all things, and we must work towards a conception of him by thinking analogically about the things in the world of which we have experience. The way in which al-Ghazali talks about God seems to be in line with religion, but really it involves treating the deity as someone much like ourselves but more so, and as a plurality of predicates rather than a complete unity. Ibn Rushd goes along with Aristotle’s argument that there can be no priority or posteriority within the same genus (see Aristotle §§7-8), and so develops a theory of meaning which is based upon the *pros hen* notion of equivocation rather than the genus-species relation. We can use the same language about God as we use about ourselves, but we should realize that the latter type of use is derivative upon the former, since the latter concepts are aspects of the paradigm which is to be found when we talk about God. When we use the same concept to refer to God and to ourselves we are speaking not univocally but equivocally, acknowledging the very real difference which exists between the level of the human and the level of the divine.

4 The main debate

In al-Ghazali’s concept of meaning, the appropriate people to interpret religious texts are those professionally involved in the religion, such as theologians, jurisprudents and so on. They need to understand the religious context of the text and apply the terms univocally to God and to his creatures. The correct way to think analytically is to adopt the methodology of the thought-experiment, holding ideas together in the imagination to see if they can be combined without contradiction. If we can imagine dead people being resurrected and leaving their graves to continue a physical existence somewhere else, in hell or paradise, then there is nothing impossible about that idea and there is no need to suggest that it is a metaphorical or equivocal reference to something else. If the Qur’an refers to physical resurrection, and if we can think about physical resurrection without contradiction, then why not just accept that what is meant by physical resurrection is what we would normally understand by that miraculous event?

It follows from Ibn Rushd’s approach that the best people to interpret difficult theological passages are not the

theologians but the philosophers, since only the latter are skilled in understanding analytical and demonstrative thought. The philosopher can understand how a religious text may embody a whole range of meanings, some intended for a more sophisticated audience and some designed for a more naïve and practically-oriented audience. The latter might understand by physical resurrection that the consequences of what we do outlive us, and the moral status of what we do affects us in this life and others after we are dead. They might find this easier to understand if they can think of themselves, or something like themselves, surviving their death. The more sophisticated audience would understand by the religious text what the philosophers understand by it, what it really means. This sort of audience does not require the rhetorical and poetic language which is capable of moving the largest section of the community to action. Only philosophers are capable of resolving the meaning of a text once and for all. The other theoreticians who work within the Islamic sciences, such as theology and jurisprudence, will constantly disagree about the appropriate meaning, and as a result they will sow discord in the community. The role of the philosopher is to resolve the meaning of the text and then communicate that meaning to different kinds of audiences in different kinds of ways, each suited to the limitations of the audience to understand the real point of the text.

It can thus be seen that the issue of meaning in Islamic philosophy concerns not only the philosophy of language but also politics. It is linked to the question as to who is entitled to derive the meanings of a text and how that meaning may be communicated to others. Although the focus of discussion is generally on the relationship between ordinary language and language about God, it has far broader implications, and leads to a diversity of views on how to do philosophy itself.

Meaning, Indian theories of

The term artha *in Sanskrit is used for the notion of meaning, in the widest sense of the word 'meaning'; it can be the meaning of words, sentences and scriptures, as well as of nonlinguistic gestures and signs. Its meaning ranges from a real object in the external world referred to by a word to a mere concept of an object which may or may not correspond to anything in the external world. The differences regarding what 'meaning' is are argued out by the philosophical schools of Nyāya, Vaiśeṣika, Mīmāṃsā, Buddhism, Sanskrit grammar and Sanskrit poetics. Among these, Nyāya, Vaiśeṣika and Mīmāṃsā have realistic ontologies. Mīmāṃsā focuses mainly on interpreting the Vedic scriptures. Buddhist thinkers generally depict language as giving a false picture of reality. Sanskrit grammar is more interested in language than in ontology, while Sanskrit poetics focuses on the poetic dimensions of meaning.*

Generally, the notion of meaning is stratified into three or four types. First there is the primary meaning. If this is inappropriate in a given context, then one moves to a secondary meaning, an extension of the primary meaning. Beyond this is the suggested meaning, which may or may not be the same as the meaning intended by the speaker. Specific conditions under which these different varieties are understood are discussed by the schools.

The various Indian theories of meaning are closely related to the overall stances taken by the different schools. Among the factors which influence the notion of meaning are the ontological and epistemological views of a school, its views regarding the role of God and scripture, its focus on a certain type of discourse, and its ultimate purpose in theorizing.

1 *Artha* in different Indian traditions

The most common Sanskrit term for meaning is *artha*. In the Western literature on the notion of meaning in the Indian tradition, various terms, such as 'sense', 'reference', 'denotation', 'connotation', 'designatum' and 'intension', have been used to render the Sanskrit. However, these terms carry specific nuances of their own, and no single term adequately conveys the idea of *artha*. *Artha* basically refers to the object signified by a word. In numerous contexts, it stands for an object in the sense of an element of external reality. For instance, Patañjali (second century BC) says that when a word is pronounced, an *artha*, 'object', is understood. So in the case of 'Bring a bull' and 'Eat yoghurt', it is the *artha* that is brought in and the *artha* that is eaten.

The logicians and ontologists belonging to the schools of Nyāya and Vaiśeṣika, and the later combined school of Nyāya-Vaiśeṣika, set up an ontology containing substances, qualities, actions, relations, generic and particular properties, and absences (see Nyāya-Vaiśeṣika §§4-5). With this realistic ontology in mind, they argue that if the relation between a word and its *artha* were a natural ontological relation, there should be real experiences of burning and cutting in one's mouth after hearing words like *agni* ('fire') and *asi* ('sword'). Therefore this relation must be a conventional one (*saṃketa*), the convention being established by God as part of his initial acts of creation. The relationship between a word and the object it refers to is thought to be the desire of God that such-and-such a word should refer to such-and-such an object. It is through this established conventional relationship that a word reminds the listener of its meaning.

The school of Mīmāṃsā represents the tradition of the exegesis of the scriptural Vedic texts (see Mīmāṃsā). However, in the course of discussing and perfecting principles of interpretation, this school developed a full-scale theory of ontology and an important theory of meaning. For the Mīmāṃsakas, the primary tenets are that the Vedic scriptural texts are eternal and uncreated, and that they are meaningful. In this orthodox system, which remarkably defends the scriptures but dispenses with the notion of God, the relationship between a word and its meaning is innate and eternal. Both Nyāya-Vaiśeṣikas and Mīmāṃsakas regard language as referring to external states of the world and not just to conceptual constructions.

While the various schools of Buddhism differ among themselves concerning the nature of the external world, they all seem to agree that language relates only to a level of conceptual constructions which have no direct relationship to the actual state of the world. The tradition represented by Theravāda and the Vaibhāṣikas argued that a word refers to a thing which, in reality, is nothing but a composite entity made up of components which are momentary and in a continual flux (see Momentariness, Buddhist doctrine of). The components, the momentary atomic

elements (*dharma*), are presumed to be more real, but words do not refer to this level of reality. Thus language gives us a less than true picture of what is out there. Other schools of Buddhism, such as Vijñānavāda, reduced everything to fleeting states of consciousness (*vijñāna*). From this point of view, the objects referred to by words are not even composites. They are more like fictions (*vikalpa*) or illusions (*māyā*) created by a magician. The Mādhyamika school of Buddhism focused on the essential emptiness (*śūnyatā*) of all objects which are subject to dependent origination (*pratītyasamutpāda*). This also leaves language far away from the level of reality, which in this case is the level of emptiness (see Buddhist concept of Emptiness). Later Buddhist logicians, such as Dignāga, developed a theory of word-meaning which we can call the 'exclusionary' theory of meaning (*apoha*). Briefly stated, if a word refers only to a conceptual construction, and not to a state of reality, then how are we to construe the conceptual construction? The *apoha* theory proposed by the Buddhist logicians says that external reality ultimately consists of momentary atomic elements which are so individualized and unique (*svalakṣaṇa*) that they are beyond perception and characterization. Our perceptions and conceptions involve generalization (*sāmānyalakṣaṇa*), and hence do not correspond to reality. A concept which corresponds to a given word must be finally construed as being nothing more than the exclusion of all other concepts. This theory ultimately says that all concepts are different from each other, and yet they cannot be defined by making a reference to any level of reality (see Nominalism, Buddhist doctrine of).

The tradition of the grammarians, beginning with Bhartṛhari (fifth century), seems to have followed a middle path between the realistic theories of reference (*bāhyārthavāda*) developed by Nyāya-Vaiśeṣika and Mīmāṃsā on the one hand, and the notional/conceptual theories (*vikalpa*) of the Buddhists on the other. For them, the meaning of a word is closely related to the level of understanding. Whether or not things are real, we do have concepts. These concepts form the content of a person's cognitions derived from language. Without necessarily denying the external reality of objects in the world, the grammarians claimed that the meaning of a word is only a projection of intellect (*bauddhārtha*, *buddhipratibhāsa*). The examples they offer, such as *śaśasṛōga* ('horn of a rabbit') and *vandhyāsuta* ('son of a barren woman'), remain meaningful within this theory. The Sanskrit grammarians are thus not concerned with the truth-functional value of linguistic expressions. For them, the truth of an expression and its meaningfulness are not to be equated.

2 Varieties of meaning

By the middle of the second millennium AD, a certain uniformity came about in the technical terminology used by different schools. The prominent schools in this period were the new school of Nyāya - Navya-Nyāya - initiated by Gaōgeśa, and the schools of Mīmāṃsā, Vedānta, and Sanskrit grammar. While all these schools engaged in pitched battles against each other, they seem to have accepted the terminological lead of the neo-logicians, the Navya-Naiyāyikas. Following the discussion of *artha* by the neo-logician Gadādhara, we can state the general framework of a semantic theory. Other schools accepted this general terminology, with some variations.

It may be said that the term *artha* stands for the object or content of a verbal cognition or a cognition which results from hearing a word (*śābdabodhaviṣaya*). Such a verbal cognition results from the cognition of a word (*śābdajñāna*) on the basis of an awareness of the signification function pertaining to that word (*padaniṣṭhavṛttijñāna*). Depending upon the kind of signification function (*vṛtti*) involved in the emergence of the verbal cognition, the meaning belongs to a distinct type. In general terms:

1 When a verbal cognition results from the primary signification function (*śakti*/*abhidhāvṛtti*/*mukhyavṛtti*) of a word, the object or content of that cognition is called primary meaning (*śakyārtha*/*vācyārtha*/*abhidheya*).
2 When a verbal cognition results from the secondary signification function (*lakṣaṇāvṛtti*/*guṇavṛtti*) of a word, the object or content of that cognition is called secondary meaning (*lakṣyārtha*).
3 When a verbal cognition results from the suggestive signification function (*vyañjanāvṛtti*) of a word, the object or content of that cognition is called suggested meaning (*vyaōgyārtha/dhvanitārtha*).
4 When a verbal cognition results from the intentional signification function (*tātparyavṛtti*) of a word, the object or content of that cognition is called intended meaning (*tātparyārtha*).

Not all schools of Indian philosophy accept all of these different kinds of signification functions for words, and they hold substantially different views on the nature of words, meanings, and the relations between words and meanings. However, the above terminology holds true, in general, for most of the schools. Let us note some of the

important differences. Mīmāṃsā claims that the sole primary meaning of the word ‘bull’ is the generic or class property (*jāti*) - ‘bullness’, say - and the individual object which possesses this generic property, namely a particular bull, is only secondarily and subsequently understood from the word ‘bull’. The school called Kevalavyaktivāda, a segment of the Nyāya school, argues that a particular individual bull is the sole primary meaning of the word ‘bull’, while the generic property bullness is merely a secondary meaning. Nyāya generally argues that the primary meaning of a word is an individual object qualified by a generic property (*jātiviśiṣṭavyakti*), both being perceived simultaneously.

Sanskrit grammarians distinguish between various different kinds of meanings (*artha*). The term *artha* stands for an external object (*vastumātra*), as well as for the object that is intended to be signified by a word (*abhidheya*). The latter - that is, meaning in a linguistic sense - can be meaning in a technical context (*śāstrīya*), such as the meaning of an affix or a stem, or it can be meaning as understood by people in actual communication (*laukika*). Then there is a further distinction. Meaning may be something directly intended to be signified by an expression (*abhidheya*), or it can be something which is inevitably signified (*nāntarīyaka*) when something else is really the intended meaning. Everything that is understood from a word on the basis of some kind of signification function (*vṛtti*) is covered by the term *artha*. Different systems of Indian philosophy differ from each other over whether a given cognition is derived from a word on the basis of a signification function, through inference (*anumāna*), or through presumption (*arthāpatti*). If a particular item of information is deemed to have been derived through inference or presumption, it is not included in the notion of word-meaning.

3 Other dimensions of *artha*

The scope of *artha* is actually not limited in Sanskrit texts to what is usually understood as the domain of semantics in the Western literature. It covers elements such as gender (*liōga*) and number (*saṃkhyā*), as well as such semantic/syntactic roles (*kāraka*) as ‘agentness’ (*kartṛtva*) and ‘objectness’ (*karmatva*). Tenses such as the present, past and future, and moods such as the imperative and optative are also traditionally included in the *arthas* signified by a verb root or an affix.

Another aspect of the concept of *artha* is revealed in the theory of *dyotyārtha*, ‘co-signified’ meaning. According to this theory, to put it in simple terms, particles such as *ca* (‘and’) do not have any lexical or primary meaning. They are said to help other words used in constructions with them to signify special aspects of their meaning. For instance, in the phrase ‘John and Tom’, the meaning of grouping is said to be not directly signified by the word ‘and’. The theory of *dyotyārtha* argues that grouping is a specific meaning of the two words ‘John’ and ‘Tom’, but that these two words are unable to signify it if used by themselves. The word ‘and’ used along with them is said to work as a catalyst that enables them to signify this special meaning.

The problem of use and mention of words is also handled by Sanskrit grammarians by treating the word itself as a part of the meaning it signifies. This is a unique way of handling this problem.

4 Different views regarding sentence-meaning

Most schools of Indian philosophy have an atomistic view of meaning and the meaning-bearing linguistic unit. This means that a sentence is put together by combining words and words are put together by combining morphemic elements such as stems, roots and affixes. The same applies to meaning. The word-meaning may be viewed as a fusion of the meanings of stems, roots and affixes, and the meaning of a sentence may be viewed as a fusion of the meanings of its constituent words. Beyond this generality, different schools have specific proposals. The tradition of Prābhākara Mīmāṃsā proposes that the words of a sentence already convey contextualized/connected meanings (*anvitābhidhāna*) and that the sentence-meaning is not different from a simple addition of these inherently connected word-meanings. On the other hand, the Naiyāyikas and the Bhāṭṭa Mīmāṃsakas propose that the words of a sentence taken by themselves convey uncontextualized/unconnected meanings, and that these uncontextualized word-meanings are subsequently brought into a contextualized association with each other (*abhihitānvaya*). Therefore, sentence-meaning is different from word-meanings, and is communicated through the concatenation (*saṃsarga*) of words rather than by the words themselves. This is also the view of the early grammarians such as Patañjali and Kātyāyana.

For the later grammarian-philosopher Bhartṛhari, however, there are no divisions in speech acts and in

communicated meanings. He says that only a person ignorant of the real nature of language believes the divisions of sentences into words, stems, roots and affixes to be real. Such divisions are useful fictions and have an explanatory value in grammatical theory, but have no reality in communication. In reality, there is no sequence in the cognitions of these different components. The sentence-meaning becomes an object or content of a single flash of cognition (*pratibhā*).

5 Some important conceptions

The terms *śakyatāvacchedaka* and *pravṛttinimitta* signify a property which determines the inclusion of a particular instance within the class of possible entities referred to by a word. It is a property whose possession by an entity is the necessary and sufficient condition for a given word to be used to refer to that entity. Thus the property of potness may be viewed as the *śakyatāvacchedaka* controlling the use of the word 'pot'.

Lakṣaṇāvṛtti (the 'secondary signification function') is invoked in situations where the primary meaning of an utterance does not appear to make sense in view of the intention behind the utterance, causing one to look for a secondary meaning. However, the secondary meaning is always something that is related to the primary meaning in some way. For example, the expression *gaōgāyāṃ ghoṣaḥ* literally refers to a colony of cowherds on the river Ganges. Here it is argued that one obviously cannot have a colony of cowherds sitting on top of the Ganges. This would clearly go against the intention of the speaker. Thus there is both a difficulty in justifying the linkage of word-meanings (*anvayānupapatti*) and a difficulty in justifying the literal or primary meaning in relation to the intention of the speaker (*tātparyānupapatti*). These interpretive difficulties nudge one away from the primary meaning of the expression to a secondary meaning which is related to that primary meaning. Thus we understand the expression as referring to a colony of cowherds on the *bank* of the Ganges.

It is the third level of meaning, or *vyañjanāvṛtti* ('suggestive signification function'), which is analysed and elaborated by authors such as Ānandavardhana (ninth century) in the tradition of Sanskrit poetics. Consider the following instance of poetic suggestion. Her husband away on a long journey, a lovelorn young wife instructs a visiting young man: 'My dear guest, I sleep here and my nightblind mother-in-law sleeps over there. Please make sure you do not stumble at night.' The suggested meaning is an invitation to the young man to come and share her bed. Thus the poetic aspect of language goes well beyond the levels of lexical and metaphorical meanings, and heightens aesthetic pleasure through such suggestions.

6 Why the differences?

The nuances of these different theories are closely related to the markedly different interests of the schools within which they developed. Scholars of Sanskrit poetics were interested in the poetic dimensions of meaning. Grammarians were interested in language and cognition, but had little interest in ontology. For them, words and meanings had to be explained irrespective of one's metaphysical views. Nyāya-Vaiśeṣikas were primarily interested in logic, epistemology and ontology, and argued that a valid sentence was a true picture of a state of reality. The foremost goal of Mīmāṃsā was to interpret and defend the Vedic scriptures. Thus, for Mīmāṃsā, meaning had to be eternal, uncreated and unrelated to a person's intention, because its word *par excellence*, the Vedic scriptures, was eternal, uncreated and beyond any authorship, divine or human. The scriptural word was there to instruct people on how to perform proper ritual and moral duties. The Buddhists, on the other hand, aimed at weaning people away from all attachment to the world, and hence at showing the emptiness of everything, including language. They were more interested in demonstrating how language fails to portray reality, than in explaining how it works. The theories of meaning were thus a significant part of the total agenda of each school and need to be understood in their specific contexts.

Measurement, theory of

A conceptual analysis of measurement can properly begin by formulating the two fundamental problems of any measurement procedure. The first problem is that of representation, justifying the assignment of numbers to objects or phenomena. We cannot literally take a number in our hands and 'apply' it to a physical object. What we can show is that the structure of a set of phenomena under certain empirical operations and relations is the same as the structure of some set of numbers under corresponding arithmetical operations and relations. Solution of the representation problem for a theory of measurement does not completely lay bare the structure of the theory, for there is often a formal difference between the kind of assignment of numbers arising from different procedures of measurement. This is the second fundamental problem, determining the scale type of a given procedure.

Counting is an example of an absolute scale. The number of members of a given collection of objects is determined uniquely. In contrast, the measurement of mass or weight is an example of a ratio scale. An empirical procedure for measuring mass does not determine the unit of mass. The measurement of temperature is an example of an interval scale. The empirical procedure of measuring temperature by use of a thermometer determines neither a unit nor an origin. In this sort of measurement the ratio of any two intervals is independent of the unit and zero point of measurement.

Still another type of scale is one which is arbitrary except for order. Moh's hardness scale, according to which minerals are ranked in regard to hardness as determined by a scratch test, and the Beaufort wind scale, whereby the strength of a wind is classified as calm, light air, light breeze, and so on, are examples of ordinal scales.

A distinction is made between those scales of measurement which are fundamental and those which are derived. A derived scale presupposes and uses the numerical results of at least one other scale. In contrast, a fundamental scale does not depend on others.

Another common distinction is that between extensive and intensive quantities or scales. For extensive quantities like mass or distance an empirical operation of combination can be given which has the structural properties of the numerical operation of addition. Intensive quantities do not have such an operation; typical examples are temperature and cardinal utility.

A widespread complaint about this classical foundation of measurement is that it takes too little account of the analysis of variability in the quantity measured. One important source is systematic variability in the empirical properties of the object being measured. Another source lies not in the object but in the procedures of measurement being used. There are also random errors which can arise from variability in the object, the procedures or the conditions surrounding the observations.

1 First fundamental problem: representation

Since the days of the Greek geometers, mathematicians, philosophers and empirical scientists have been discussing the nature of measurement. Eudoxus' development of the theory of proportion, which forms the substance of Book V of Euclid's *Elements,* is probably the first sustained analysis directly relevant to measurement. A systematic approach to the subject of measurement may well begin by formulating the two fundamental problems of any procedure of measurement. The first problem is to justify the assignment of numbers to objects or phenomena.

The early history of mathematics shows how difficult it was to divorce arithmetic from particular empirical structures. Thus the early Egyptians could not think of $2 + 3$, but only of 2 bushels of wheat plus 3 bushels of wheat. From a logical standpoint, there is just one arithmetic of numbers, not an arithmetic for bushels of wheat, and a separate arithmetic for quarts of milk. The first problem for a theory of measurement is to show how this one arithmetic of numbers may be applied in a variety of empirical situations. This is done by showing that the relevant structure of the empirical situation investigated is isomorphic to an arithmetical structure. The purpose of the definitions of isomorphism given for each kind of measurement considered is to make the rough-and-ready intuitive idea of same structure precise. The great significance of finding such an isomorphism of structures is that we may then use all our familiar knowledge of computational methods, as applied to the arithmetical structure, to infer facts about the isomorphic empirical structure.

A procedure of measurement is needed in any area of science when we desire to pass from simple qualitative observations to the quantitative observations necessary for the precise prediction or control of phenomena. To justify this transition we need an algebra of empirically realizable operations and relations which can be shown to be isomorphic to an appropriately chosen numerical algebra. Satisfying this requirement is the fundamental problem of measurement representation.

2 Second fundamental problem: uniqueness

Solution of the representation problem for a theory of measurement is not enough. There is often a formal difference between the kind of assignment of numbers arising from different procedures of measurement. Consider the following three statements:

(1) The number of people now in this room is seven.
(2) Yesterday John weighed 150 lbs.
(3) The maximum temperature tomorrow will be $89°\mathrm{F}$.

Here we may formally distinguish three kinds of measurement. Counting is an example of an ’absolute’ scale. The number of members of a given collection of objects is determined uniquely. There is no arbitrary choice of a unit or zero available. In contrast, the measurement of mass or weight is an example of a ’ratio’ scale. Empirical procedures for measuring mass do not determine the unit of mass. The choice of a unit is an empirically arbitrary decision, but the ratio of any two masses is independent of such choice. The measurement of distance is a second example of a ratio scale. The ratio of the distance between Palo Alto and San Francisco to the distance between Washington and New York is the same whether the measurement is made in miles or metres.

The measurement of temperature is an example of an interval scale. The empirical procedure of measuring temperature by use of a thermometer determines neither a unit nor an origin. In this sort of measurement the ratio of any two intervals is independent of the unit and zero point of measurement. Examples other than measurement of temperature are measurements of temporal dates, geographical longitude and cardinal utility.

In terms of the notion of absolute, ratio and interval scales we may formulate the second fundamental problem for a theory of measurement: determine the scale type of the measurements resulting from the procedure. (A detailed treatment of the theory of fundamental measurement from the standpoint of these two central problems is to be found in Krantz *et al*. the three-volume treatise *Foundations of Measurement*, 1971, 1989, 1990.)

3 Classification of scales of measurement

For the purpose of systematizing some of the discussion of the uniqueness problem in the previous section, we may define a scale as a class of measurement procedures having the same transformation properties. Examples of three different scales have already been mentioned, namely, counting as an absolute scale, measurement of mass as a ratio scale and measurement of temperature as an interval scale.

An ’ordinal’ scale is one which is arbitrary except for order. A number is assigned to give a ranking. The social sciences extensively use such scales. Numbers are also sometimes used for naming or classification. The numerical assignment is completely arbitrary. The numbers on football players’ shirts are examples of this sort of measurement. Such scales are usually called ’nominal’ scales.

In the literature a distinction is often made between those scales of measurement which are fundamental and those which are ’derived’. A derived scale is one which in the procedure of measurement presupposes and uses the numerical results of at least one other scale. In contrast, a ’fundamental’ scale does not depend on other scales. As might be expected, foundational investigations of measurement have been primarily concerned with fundamental scales, and such is the emphasis here (Krantz *et al.* 1971: ch. 10).

Another distinction common in the literature is that between extensive and intensive quantities or scales. For extensive quantities an empirical operation of combination can be given which has the structural properties of the numerical operation of addition. Intensive quantities are characterized by the absence of such an operation.

There is a fairly large literature on the problem of characterizing in what sense fundamental measurement of intensive quantities is possible. An early, significant example is the analysis of Nicole Oresme in the fourteenth

century.

4 Measurement and theory construction

It has become a platitude of scientific method that measurement of some attribute is really only interesting if some theory about that attribute is available. It is common to criticize many psychometric scales in psychology on the ground that application of the scales leads nowhere. Put another way, the criticism is that measurement for measurement's sake is not very fruitful scientifically.

There are two other aspects of the relation between measurement and theory construction that are important and yet are somewhat neglected. The first is that a theory of measurement for some characteristic of empirical phenomena is itself a genuine scientific theory. Moreover, certain theories are practically coextensive with the theory of measurement of the quantities basic to the theory. For example, the heart of the theory of rational behaviour in situations of limited information is the measurement of subjective probability and utility (see Decision and game theory §2).

The second aspect is that the chief stumbling block to applying certain theories is a problem of measurement. A classical example in physics is the general theory of relativity. Of the three 'traditional' pieces of evidence for the general theory, namely, the advancement of the perihelion of Mercury, the deflection of light waves by the gravitational field of the sun, and the red shift of stellar spectra, only the first does not present really difficult measurement problems (see Einstein, A. §3).

5 Ordinal theory of measurement

As a simple example of fundamental measurement, we may consider the ordinal theory of measurement. Models of this theory are customarily called weak orderings, defined as follows. Let A be a nonempty set and R a binary relation on this set. A pair (A, R) is a 'simple relation structure'. A simple relation structure (A, R) is a 'weak ordering' if and only if for every x, y and z in A (i) if xRy and yRx then xRz, and (ii) xRy or yRx.

The definition of isomorphism of simple relation structures illustrates nicely the general concept. A simple relation structure (A, R) is 'isomorphic' to a simple relation structure (A', R') if and only if there is a function f such that (i) the domain of f is A and the range of f is A', (ii) f is a one-one function, and (iii) if x and y are in A then xRy if and only if $f(x)R'f(y)$. To illustrate this definition of isomorphism let us consider the question: 'are any two finite weak orderings with the same number of elements isomorphic?' Intuitively it is clear that the answer is negative, because in one of the weak orderings all the objects can stand in the relation R to each other and not so in the other.

Homomorphism of models. In many cases a representation theorem in terms of isomorphism of models turns out to be less interesting than a representation theorem in terms of the weaker notion of homomorphism. Good examples are provided by theories of measurement. As already noted, when we consider general practices of measurement it is evident that in terms of the structural notion of isomorphism we would, roughly speaking, think of the isomorphism as being established between an empirical model of the theory of measurement and a numerical model. However, a slightly more detailed examination of the question indicates that difficulties about isomorphism quickly arise. In all too many cases of measurement, distinct empirical objects or phenomena are assigned the same number, and thus the one-one relationship required for isomorphism of models is destroyed. Fortunately, this weakening of the one-one requirement for isomorphism is the only respect in which we must change the general notion, in order to obtain an adequate account for theories of measurement of the relation between empirical and numerical models. The general notion of homomorphism is designed to accommodate exactly this situation. To obtain the formal definition of homomorphism for two simple relation structures as previously defined, we need only drop the requirement that the function establishing the isomorphism be one-one.

The concept of homomorphism is what we need to state a representation theorem for weak orders. First, a 'numerical' weak ordering is a weak ordering (A, $\leq$) where A is a set of numbers. The selection of the numerical relation $\leq$ to represent the relation R in a weak ordering is arbitrary, in the sense that the numerical relation $\geq$ could just as well have been chosen. However, choice of one of the two relations $\leq$ or $\geq$ is the only intuitively sound possibility. The following theorem provides a homomorphic representation theorem for finite weak orderings, and thus makes the theory of finite weak orderings a theory of measurement:

(1) Every finite weak ordering is homomorphic to a numerical weak ordering.

(1) was restricted to finite weak orderings for good reason: it is false if this restriction is removed. In order to state the desired theorem for the infinite case one preliminary notion is needed. Let (*A*, *R*) be a simple relation structure, and let *B* be a subset of *A*. Define the strict ordering relation *P* in terms of *R* by the equivalence: xPy if and only if xRy and not yRx. Then we say that *B* is *R-order-dense* in *A* if and only if for every *x* and *y* in *A* and not in *B* such that xPy there is a *z* in *B* such that xRz and zRy. Note that the denumerable set of rational numbers is order-dense in the non-denumerable set of all real numbers with respect to the natural numerical ordering $\leq$. This relationship between the denumerable rational numbers and all real numbers is just the one that is necessary and sufficient for the existence of a homomorphism between an infinite and a numerical weak ordering.

(2) Let (*A*, *R*) be an infinite weak ordering. Then a necessary and sufficient condition that it be homomorphic to a numerical weak ordering is that there is a denumerable subset *B* of *A* such that (i) *B* is *R*-order-dense in *A* and (ii) no two elements of *B* stand in the relation *E*, for example, for any distinct *x* and *y* in *B* either not xRy or not yRx.

The proof is related to the classical ordinal characterization of the continuum by Cantor (1895) (see Continuum hypothesis). The formulation and proof of (2) uses more mathematical apparatus than elementary logic. The restriction of the discussion of theoretical issues in the philosophy of science to the framework of first-order logic has too often meant a restriction of the extent to which the discussion could come into contact with other than highly simplified scientific theories especially constructed for the purpose at hand. An advantage of the set-theoretical formulation of theories such as theories of measurement is that standard mathematical methods are immediately available for both the formulation of the theory and the deductive analysis of the structure of its models (see Theories, scientific §3).

6 Invariance and meaningfulness

As already mentioned, the number assigned to measure mass is unique once a unit has been chosen. A more technical way of putting this is that the measurement of mass is unique up to a similarity transformation. A numerical function is a similarity transformation if there is a positive number αsuch that for every real number *x*, $\phi(x) = \alpha x$. In transforming from pounds to grams, for instance, the multiplicative factor α is 453.6. The measurement of temperature in $^\circ\mathrm{C}$ or F has different characteristics. Here an origin as well as a unit is arbitrarily chosen. Technically speaking, the measurement of temperature is unique up to a linear transformation. A numerical function is a 'linear' transformation if there are numbers α and β with $\alpha > 0$ such that for every number *x*, $\phi(x) = \alpha x + \beta$. In transforming from centigrade to Fahrenheit degrees of temperature, for instance, $\alpha = 9/5$ and $\beta = 32$.

Ordinal measurements are commonly said to be unique up to a monotone increasing transformation. A numerical function is a monotone increasing transformation if, for any two numbers *x* and *y*, if $x < y$, then $\phi(x) < \phi(y)$. Such transformations are also called 'order-preserving'.

An empirical hypothesis, or any statement in fact, which uses numerical quantities is empirically meaningful only if its truth value is invariant under the appropriate transformations of the numerical quantities involved. As an example, suppose a psychologist has an ordinal measure of IQ, and thinks that scores $S(a)$ on a certain new test *T* have ordinal significance in ranking the intellectual ability of people. Suppose further that the psychologist is able to obtain the ages $A(a)$ of the subjects. The question then is: should the following hypothesis be regarded as empirically meaningful? For any subjects *a* and *b*, if $S(a)/A(a) < S(b)/A(b)$, then $\mathrm{IQ}(a) < \mathrm{IQ}(b)$. From the standpoint of the invariance characterization of empirical meaning, the answer is negative. To see this, let $\mathrm{IQ}(a) \geq \mathrm{IQ}(b)$, let $A(a) = 7$, $A(b) = 12$, $S(a) = 3$, $S(b) = 7$. Make no transformations on the IQ data, and make no transformations on the age data. But let be a monotone-increasing transformation of the ordinal measurements $S(a)$ which carries 3 into 6 and 7 into 8. Then we have $3/7 < 7/12$, but $6/7 \geq 8/12$, and the truth value of the hypothesis is not invariant under .

The empirically significant thing about the transformation characteristic of a quantity is that it expresses in precise form how unique is the structural isomorphism between the empirical operations used to obtain a given measurement and the corresponding arithmetical operations or relations. If, for example, the empirical operation is simply that of ordering a set of objects according to some characteristic, then the corresponding arithmetical

relation is that of less than (or greater than), and any two functions which map the objects into numbers in a manner preserving the empirical ordering are adequate. Only those arithmetical operations and relations which are invariant under monotone transformations have empirical significance in this situation.

We can easily state the uniqueness or invariance theorem corresponding to the representation theorem (1) for finite weak orders:

(3) Let (*A*, *R*) be a finite weak order. Then any two numerical weak orderings to which it is homomorphic are related by a monotone-increasing transformation.

Put in other language, the numerical representation of finite weak orders is unique up to an ordinal transformation. Invariance up to ordinal transformations is not a very strong property of a measurement, and it is for this reason that the hypothesis considered above turned out not to be meaningful, because it was not invariant under monotone transformations of the measurement data.

A measurement representation theorem should ordinarily be accompanied by a matching invariance theorem stating the degree to which a representation of a structure is unique. In the mathematically simple and direct cases of measurement it is usually easy to identify the invariant group of transformations. For more complicated structures, for example structures that satisfy the axioms of a scientific theory, it may be necessary to introduce more complicated apparatus, such as the Galilean or Lorentz transformations of physics, but the objective is the same, namely, to characterize meaningful concepts in terms of invariance.

One point needs emphasis. When the concepts are given in terms of the representation, for example a numerical representation in the case of measurement, or representation in terms of Cartesian coordinates in the case of geometry, a test for invariance is needed. When purely qualitative relations are given which are defined in terms of the qualitative primitives of a theory, for example those of measurement or geometry, then it follows at once that the defined relations are invariant and therefore meaningful. On the other hand, the great importance of the representations and the reduction in computations and notation they achieve, as well as understanding of structure, make it imperative that we have a clear understanding of invariance and meaningfulness for representations which may be, in appearance, rather far removed from the qualitative structures that constitute models of the theory (Krantz *et al* 1990: ch. 22).

7 Variability, thresholds and errors

In the standard theory of fundamental measurement as discussed, qualitative axioms are formulated that lead to a numerical assignment unique up to some simple transformation. A widespread complaint about this classical foundation of measurement is that it takes too little account of the analysis of variability in the quantity measured. The sources of such variability can be of several different kinds. One important source is simply variability in the empirical properties of the object being measured. The height of a person for example varies on a diurnal basis and the variability of the weight of a person from day to day is a familiar fact of everyday experience. A quite different source of variability lies not in the object being measured but in the procedures of measurement being used. When the procedures being used lead to variability, these are ordinarily attributed to error. The study of error, especially in physical measurements goes back to the eighteenth century with fundamental work by Simpson, Lagrange, Laplace and, especially, Gauss. In the physical sciences the standard reporting of statistical errors in scientific publications began about the middle of the nineteenth century, especially in the publication of astronomical observations.

At least five kinds of error have been distinguished in astronomical observation, and they illustrate nicely the kind of analysis that can be made of errors in other empirical observations, even though changes in focus must be made when the empirical phenomena are quite different. For astronomers there are instrumental errors arising from imperfections in the production of the instruments of observation used such as telescopes and clocks. There are personal errors due to the response characteristics of the observer, for instance, coordinating a visual observation with the auditory beat of a clock, or with the nearly simultaneous visual observation of a clock, will lead to slightly different results for different observers. One example, Nevil Maskelyne, the fifth astronomer royal of Great Britain, discharged his assistant in 1796 because the assistant had observed the transits of stars and planets about a half-second later than Maskelyne himself. An objective of modern technology is to eliminate as much as possible

such personal errors, but they certainly persist in many areas of empirical observation. Errors of the third kind are 'systematic' and are due to conditions that are themselves subject to observation and measurement. For example, steady winds in a given direction must be taken account of in many kinds of familiar procedures, such as a navigator setting a course of a ship or aeroplane. Fourth, there are 'random' errors which can arise from variability in the conditions surrounding the observations and are not necessarily due either to variations in the object being measured or in the procedures of measurement. Meteorological variations affecting astronomical observations are a good example. Of a different sort, and a fifth kind, are empirical errors of 'computation' once numerical observations have been recorded. It is important to emphasize that there is nothing fixed and a priori about the classification given here. Other classifications can be found in the literature, but there is a natural conceptual basis to support each of the types of error listed (Taylor 1982).

It is not possible here to examine in detail how the foundational investigations of measurement procedures have been able to deal with such problems of error. One point of interest has been the analysis of thresholds in psychological judgments. It is a familiar fact that if a person is asked to judge the weight of two objects that are very close together, psychological discrimination of a difference will not occur when the difference is sufficiently small. There is a large body of work and a large body of theory connected with such psychological thresholds (Krantz *et al*. 1989: ch. 16).

A central objective of foundational analysis in this area is to begin with qualitative axioms, but to expect the representation for a measurement property of an object to be in terms of a random variable with a given probability distribution rather than in terms of a fixed numerical assignment. Such assignment of random variables rather than numbers to objects is already an abstraction from the various kinds of measurement error distinguished above. Part of the reason for this is that the main objective of such analysis is to end up with probability distributions for the errors in the form of some standard probability distributions familiar in mathematical statistics and amenable to detailed statistical treatment.

The theory of measurement has been important in quantum mechanics, the most significant physical theory of the twentieth century, for two distinct but related conceptual reasons. One arises from the Heisenberg uncertainty principle which shows that it is not possible to measure simultaneously with arbitrary precision the position and momentum of particles such as electrons or protons. Closely connected with this is the second aspect of measurement in quantum mechanics, namely the recognition that there is a physical interaction between the measurement instrument and the measurement object, a subject not really developed at all in classical physics (von Neumann 1996; see Quantum measurement problem).

In the social sciences and medicine a familiar kind of error is that which arises from finite sampling. If we wish to know something about the telephone habits, driving habits or reactions to a new medicine of a given population, we ordinarily do not plan to interview or test everyone in the population, but rather use a random sample to infer the distribution of habits or reactions in the entire population. The theory of such sampling is very much a twentieth-century subject (see Statistics and social science §2).

Mechanics, Aristotelian

The central feature of Aristotle's mechanics is his discussion of local motion, a change of place, which he categorizes as either natural or violent. He further divides natural motion into celestial motion, which is uniform, circular and eternal, and terrestrial motion, which is rectilinear (straight up or down), and finite in both time and distance. All motions which are not natural are classified as violent.

For all motion Aristotle required a force in direct contact with the object being moved. We may represent the Aristotelian law of motion by the modern formula: Velocity = Force (motive power)/Resistance, or $V = kF/R$*. In applying this law of motion to falling bodies, Aristotle associated the weight of the body with the force, and the resistance of the air (or other medium) with the resistance. Thus, Aristotle believed that heavy bodies fall faster than light ones.*

The problem of what force is actually in contact with the body, and causes it to fall, posed a serious difficulty for Aristotle. Aristotle concluded that elements were created with a tendency to move to their natural place, barring any hindrance or interference. Projectile motion posed a similar problem for Aristotle. In the case of a thrown object, the force was provided by the hand of the thrower as long as the object was in contact with the hand. But one needed an explanation of why the object continued to move once it had left the thrower's hand. Aristotle concluded that the medium through which the projectile moved provided the force that kept it moving.

Aristotle also regarded both the existence of a void or any motion in it as impossible. A void contains nothing that could sustain the motion of a projectile once it left the projector. In addition, because a void can provide no resistance, the speed of an object in a void would be infinite.

1 Local motion

This entry concentrates on Aristotle's discussion of motion and its causes as found in his work *Physics*. Aristotle's concept of motion includes not only local motion, a change of place, but any change from potential to actual being. This may include changes in shape, size, or properties of a body such as temperature or colour. The central feature of his mechanics is, however, his discussion of local motion. This includes the Aristotelian law of motion and the questions of falling bodies (and the related problem of the motion of the elements), projectile motion and the existence of a void.

Aristotle categorized local motion as either natural or violent. He further divided natural motion into celestial motion, which is uniform, circular and eternal, and terrestrial motion, which is rectilinear (straight up or down) and finite in both time and distance. The terrestrial motions are governed by the nature of the four elements which make up all substances: earth, air, fire and water, and by the idea of natural place. Earth, which is absolutely heavy, falls toward the centre of the universe (coincidently the centre of the earth), which is its natural place. Fire, which is absolutely light, rises to its natural place, a spherical shell inside the lunar sphere. Thus, the equilibrium distribution of an Aristotelian universe would be a spherical earth surrounded by concentric spherical shells of water, air and fire, surrounded by the heavens. Objects composed of a mixture of elements behave in the manner of their predominant element. All motions which are not natural are classified as violent; for example, projectile motion.

For both natural and violent motions Aristotle required a force in direct contact with the object being moved. This view that a force is necessary for motion to occur at all (everything that is moved is moved by something else) is quite different from the modern view (see Mechanics, classical). For living creatures the motive power required is provided by the soul. Celestial objects and planets are moved by celestial intelligences or spirits. Inanimate objects require a force in contact with the object itself and this posed a difficult problem in dealing with falling bodies, projectiles and with the motion of the elements themselves.

We may represent the Aristotelian law of motion by the modern formula:

$$\text{Velocity} = \text{Force (motive power)}/\text{Resistance} \quad \text{or} \quad V = kF/R.$$

Aristotle never stated his law of motion in this concise form, but rather discussed how either the distance travelled

or the time of travel will change when either the force exerted on the object or the weight of the object changes. He discussed motion in this way because the concept of speed as the ratio of distance to time was not considered a proper ratio. One could have a proper ratio only of similar things such as the ratio of one distance to another distance, or of one time to another time.

If then: the mover *A*, has moved *B*, a distance *C*, in time *D*, then in the same time force *A* will move $\frac{1}{2}B$ twice the distance *C*, and in $\frac{1}{2}D$ it will move $\frac{1}{2}B$ the whole distance *C*: thus the rules of proportion will be observed. Again if a given force move a given weight a certain distance in a certain time and half the distance in half the time, half the motive power will move half the weight the same distance in the same time. Let *E* represent half the motive power *A* and *Z* half the weight *B*: then the ratio between the motive power and the weight in the one case is similar and proportionate to the ratio in the other, so that each force will cause the same distance to be travelled in the same time (*Physics* VII 5).

It should also be emphasized that Aristotelian motion required the action of *both* the force and the resistance, discussed later.

Aristotle recognized that his law of motion did not have universal applicability. He knew that the application of a force might not result in any motion at all, even though his law of motion implies that it would, as would be the case with someone attempting to lift a very large weight. To solve the problem he added a subsidiary condition to the law that required the force to be greater than the resistance.

If, then, (a force) *A* move *B* a distance *C* in time *D*, it does not follow that *E*, being half of *A*, will in time *D*, or in any fraction of it, cause *B* to traverse a part of *C*, the ratio between which and the whole of *C* is proportionate to that between *A* and *E* (whatever fraction of *A* that *E* may be), in fact it might well be that it will produce no motion at all; otherwise one man might move a ship, since both the motive power of the ship-haulers and the distance that they all cause the ship to traverse are divisible into as many parts as there are men (*Physics* VII 5).

In applying this law of motion to falling bodies Aristotle associated the weight of the body with the force, and the resistance of the air (or other medium) with the resistance. Thus, he believed that heavy bodies fall faster than light ones. ’We see that bodies which have a greater impulse either of weight or of lightness, if they are alike in other respects, move faster over an equal space, and in the ratio which their magnitudes bear to each other’ (*Physics* IV 8).

2 The causes of motion

The problem of what force is actually in contact with the body and causes it to fall posed a serious difficulty for Aristotle. This is closely connected to the question of the natural motion of elements. What force causes earth to fall to the centre of the universe and what force causes fire to rise? Aristotle’s discussion of this question is quite complex and involves the change from potentiality to actuality, in this case from potential to actual motion (Lang 1992). Natural place is the actuality that moves the elements. Elements were created with a tendency to move to their natural place, barring any hindrance or interference.

The idea that natural place causes the motion is not an attraction to natural place (that is, up or down) or what we might call the force of gravity, even though Aristotle associated weight with the force that causes a body to fall, because either of these involves action at a distance and not a force in direct contact with the body. Whatever creates the body or element gives it an internal tendency for motion. Aristotle also knew that a falling body did not travel at constant speed, but that it did, in fact, accelerate. He did not offer any explanation of this acceleration, but the problem was considered by several of his later commentators.

Projectile motion posed a similar problem for Aristotle. In the case of a thrown object, the force was provided by the hand of the thrower as long as the object was in contact with the hand. But one needed an explanation of why the object continued to move once it had left the thrower’s hand. Aristotle concluded that the medium through which the projectile moved provided the force that kept it moving. This occurred either by *antiperistasis* (replacement), in which the medium rushes around the body to prevent the formation of a void or vacuum and pushed the body from behind, or by the medium itself having acquired the power to be a mover from the original projector. (The theory of *antiperistasis* is more probably due to Plato and his followers than to Aristotle.)

The medium itself does not have to move, but rather possesses the power to move something else. This power is, however, imperfectly transmitted from one layer of the medium to the next and gradually dies away. Thus, as indicated above, the motion of the projectile seems to be complex, consisting of both its natural motion and the motion imposed on it. It is unclear what Aristotle believed the path of a projectile was. For example, in the case of a projectile thrown horizontally, did it first travel only horizontally, and then fall to its natural place, or did it exhibit both horizontal and vertical motions simultaneously, throughout its motion?

The resistance needed for motion is provided by the resistance, or friction, of the medium, but also seems to include the mass or weight of the projectile. The resistance of the medium is necessary to prevent the motion of the projectile from being infinite in both speed and extent, an impossibility for Aristotle, as discussed below. Aristotle’s use of the medium to both sustain and resist motion seems paradoxical, and was commented on by several medieval critics.

3 The void

It is clear that Aristotle regarded both the existence of a void or any motion in it as impossible. First, a void contains nothing that could sustain the motion of a projectile once it left the projector. Second, because a void can provide no resistance, the speed of an object in a void would be infinite, or as Aristotle states, ’it moves through the void with a speed beyond any ratio’. He further argues that although heavy bodies fall faster than do light ones in a medium, they would move at the same speed in a void, which he regarded as impossible.

In proposing a clear statement of the inertial principle, Aristotle also gave a proof of it by relating the persistence of motion, or inertial motion, to the homogeneity of space. However he turned the argument around and regards it rather as a proof of the impossibility of motion in a void. The inertial consequences of such motion would be (to Aristotle) the unacceptable result of motion that is infinite in extent.

Aristotle’s physics forms the basis of subsequent medieval discussions of these questions. It is fair to say that medieval studies of motion consist of commentaries and criticisms of Aristotle’s work.

Mechanics, classical

Understood at its most general, 'classical mechanics' covers the approach to physical phenomena that dominated science from roughly the time of Galileo until the early decades of the twentieth century. The approach is usually characterized by the assumption that bodies carry an inherent mass and well-defined positions and velocities. Bodies subsist within a three-dimensional absolute space and influence one another through reciprocal forces. These objects obey the three laws of motion articulated by Isaac Newton in 1686 in a deterministic *manner: once a mechanical system is assembled, its future behaviour is rigidly fixed. Such 'classical' assumptions were eventually rejected by Einstein's theory of relativity, where the assumption of a three-dimensional Euclidean space is abandoned, and by quantum mechanics, where determinism and well-defined positions and velocity are eschewed.*

Classical mechanics is frequently characterized as 'billiard ball mechanics' or 'the theory of mechanism' on the grounds that the science treats its materials in the manner of colliding particles, or clockwork. Such stereotypes should be approached with caution because the basic framework of classical mechanics has long been subject to divergent interpretations that unpack the content of Newton's 'three laws' in remarkably different ways. These differing interpretations provide incompatible catalogues of the basic objects that are supposed to comprise the 'classical world' - are they point masses, rigid bodies or flexible substances? Or, as many writers have suggested, should mechanics not be regarded as 'about' the world at all, but merely as a source of useful but fictitious idealizations of reality?

These foundational disagreements explain why classical mechanics has often found itself entangled in metaphysics. Much of modern philosophy of science is characterized by attitudes that were originally articulated during the nineteenth century's attempts to clarify the grounds of classical mechanics.

1 Newton's laws of motion, first law

Introductory textbooks usually sketch a simple, standardized approach to the content of classical mechanics, which, for reasons discussed in §4, may be called the *point mass interpretation*. Although this interpretation is often presented as 'the correct understanding of classical mechanics', few philosophers or physicists of the classical era would have accepted this reading as adequate. Its reading not only suffers empirical difficulties; it does not describe a universe that would have been pleasing to most practitioners. The point mass reading has gained its textbook centrality largely because alternative foundations for mechanics prove resistant to easy articulation. Indeed, satisfactory alternatives were not fully developed until well into the twentieth century (largely by the engineering community, which requires a trustworthy classical basis for its endeavours). The mismatch between the conceptual simplicity of textbook orthodoxy and the expected characteristics of the subject is apt to cause students of philosophy much difficulty.

The essential content of classical doctrine is commonly held to reside in Isaac Newton's celebrated laws of motion. Unfortunately, these principles, in the form they were articulated by Newton, are subject to a surprising range of interpretations.

Electromagnetism is largely left out of account here. This is partly because 'classical' electromagnetism, as the subject is understood today, fits more neatly into a *relativistic* than a Newtonian framework. In the nineteenth century, light and other electromagnetic phenomena were regarded as vibrations within an 'ether' that was conceived as a material continuum in the manner of §6 (see Field theory, classical).

In Thompson and Tait's (1879) translation of Newton (1726), Newton's laws are: first law: every body continues in its state of rest or of uniform motion in a straight line, except insofar as it may be compelled by force to change that state. Second law: change of motion is proportional to force applied, and takes place in the direction of the straight line in which the force acts. Third law: to every action there is always an equal and contrary reaction: or, the mutual actions of any two bodies are always equal and oppositely directed.

Newton borrowed the first law, also known as 'the principle of inertia', from Galileo and Descartes (although neither would have accepted the doctrine in its fullest generality) (see Galilei, G.). According to it, the *natural motion* of a particle uninfluenced by external forces is always a straight line, whereas earlier scientists had often presumed such natural motions to be circular or directed towards a 'natural home' in the universe. 'Inertia' is the

traditional term for the tendency of a body to retain its present state of motion; it is harder to stop a cannon ball than a baseball even if they are travelling at the same velocity. From a Newtonian point of view, ‘inertia’ is simply another name for ‘mass’, but it is common to speak of ‘inertial *forces*’ as well, a notion discussed in §3.

Henri Poincaré (1902) claimed that the first law (as well as much of the rest of the Newtonian framework) does not report genuine physical content, but instead represents a mere ‘convention’ (see Poincaré, J.H. §3). Newton presumed that a Euclidean space exists independently of matter and understood his first law as delineating how free matter will move upon this geometrical stage. Poincaré objected that we can have no knowledge of spatial structure independent of the behaviour of material objects found within it. The first law is not a straightforward ‘fact’, but merely articulates a *criterion* for erecting a geometry around material objects. No empirical facts can force a rejection of Newton’s first law ‘criterion’ for the presence of ‘straight lines’, although, were the empirical facts otherwise, an alternative ‘convention’ might be favoured where the notions of geometry become coordinated to the movements of matter in a different fashion. This *conventionalism* has proved enormously influential within twentieth-century analytic philosophy and whether or not Poincaré’s implied distinction between a ‘convention’ and a ‘genuine fact of nature’ can be sustained remains a controversial issue (see Conventionalism).

Newton has been widely criticized for assuming the existence of an enduring ‘absolute space’ in the first law, because (i) the notion sounds unduly ‘metaphysical’, (ii) its presence seems inherently unobservable, or (iii) the first law (on its strongest reading) forces a principle of *Galilean relativity*: no law of nature allows a determination of whether a set of objects lies at rest in absolute space or merely moves through it at a constant velocity (reference objects that move in either of these ways define *inertial frames*). One is therefore denied any means of relocating a point in absolute space after an interval of time passes (see Space §§2-3).

During the nineteenth century, followers of Kant saw Galilean relativity as evidence that absolute space does not represent a real condition found in nature, but merely reflects an organizational structure imposed upon reality by the human mind (Poincaré’s conventionalism shares many affinities with such Neo-Kantian thinking) (see Kant, I. §5). But more sophisticated techniques articulated in the twentieth century (chiefly by Cartan) have suggested another resolution to the relativity problem: classical mechanics should follow Einstein’s lead in rejecting the notion of an enduring *space* in favour of a blend of space and time (see Spacetime). In Cartan’s reformulation, the first law is interpreted as demanding a certain geometrical structure within the melded spacetime, avoiding the unobservable aspects of Newton’s persisting space. Although this approach weakens Newton’s geometrical assumptions somewhat, it agrees that spacetime possesses objective features independently of human decision or the placement of material objects within the spacetime.

Cartan also showed that gravitation could be ‘geometrized away’ within certain classical frameworks, in imitation of the techniques of general relativity. It should be mentioned, however, that Galilean relativity was not universally accepted during the heyday of classical mechanics - various electrical effects once seemed as if they might provide criteria for detecting inertial movement within absolute space.

2 Newton’s laws of motion, second law

Newton’s second law is popularly known as ‘ $F = ma$’, where ‘*F*’ stands for ‘force’, ‘*m*’ for ‘mass’ and ‘*a*’ for ‘acceleration’. The claim is that a particle will deviate from its inertial motion only insofar as a force is imposed from without, in which case the particle will accelerate to a degree conditioned by its mass. In a modern treatment (if uncomplicated by ‘constraints’), ‘ $F = ma$’ provides the skeleton upon which the basic *equations of motion* for a collection of particles are constructed. The recipe is this:

(a) Delineate the particles whose interactions one wishes to study.
(b) Determine what kinds of specific force act between these (do they gravitationally attract one another?, do they display electrical attraction or repulsion?, and so on).
(c) For each particle *a*, decompose each of the forces that act upon *a* along a selected Cartesian axis - for example ‘ $f_x^{a,e}$ ’ might express the amount of electrical force that acts upon particle *a* along the *x*-axis.
(d) For each particle *a* and each Cartesian direction *x*, assemble all of the specific forces under (c) into a sum called the ‘total force acting upon the particle acting in direction *x*’.
(e) Set this sum of forces equal to $m\mathrm{d}^2x/\mathrm{d}t^2$ (that is, to what in the calculus is called ‘the second derivative of *a*’s location along the *x*-axis’). The upshot is a system of $3n$ second-order ordinary differential equations for a

collection of *n* particles.

The list under (b) of specific force laws active within the system of particles are called the *constitutive principles* for the system at hand; crudely speaking, they delineate the basic manner in which forces bind the collection together. The equations of motion constructed by this recipe then fix (*modulo* occasional technicalities) how the system will behave at all future times once the positions and velocities of all particles are known at some specific time (such data represent the system's 'phase' or *initial condition*). That is, the equations of motion in classical physics *determine* the future states of the system as it evolves from its initial condition (usually past states are determined as well). The determinism of classical physics is a famous bugbear of ethical philosophy. Quantum mechanics no longer accepts determinism of the classical variety, but it is doubtful whether what it substitutes is preferable from an ethical point of view (see Determinism and indeterminism; Free will).

'Determinism' is not the same as 'predictability' in any reasonable sense. It has been realized for some time that most classical systems are so complicated that no computer could possibly track their behaviour accurately for more than a few seconds. Much of the recent fascination with so-called 'chaos' has evolved from the discovery of new ways to extract useful partial information from these otherwise unpredictable systems (see Chaos theory).

The second law recipe has been described in some detail because Newton's less explicit formulation has proved a ripe source of philosophical confusion. Our 'recipe' approach becomes clearly established only within the investigations of Leonhard Euler in the eighteenth century. Expressing the principle as simply ' $F = ma$' encourages the impression that the second law is merely a definition of 'force'. This objection overlooks the non-arbitrary decomposition into specific forces required in the recipe. Some writers have complained that Newton's laws are 'empty' because they describe systems either subject to one force (the second law) or no forces at all (the first law). But no real life system is like this. In the author's evaluation, this objection, and many others like it, fails to understand the Euler recipe correctly.

But if Newton's second law is understood in this Eulerian vein, physics should be greatly concerned to specify the complete set of specific force laws used in step (b). Newton's law of universal gravitation supplies an admirable example of the kind of law needed, but, beyond that paradigm, classical physicists were somewhat lackadaisical in their efforts to fill out the missing laws (they never agreed, for example, on the nature of the forces that glue matter together). Joseph Sneed (1979) none the less sees the demand for these as yet unarticulated force laws as a vital part of the *content* of classical physics - he hopes that Thomas Kuhn's celebrated notion of a 'scientific paradigm' can be clarified in this manner. In truth, the constraint tradition, described in §5, often herded the actual development of mechanics in directions other than the hypothesized search for specific force laws. As we shall see, the criticism of ' $F = ma$' as an empty definition gains a greater cogency under the point of view of this school.

In general, many of the standard objections to Newton's laws originally grew out of substantial disputes over the fundamental trustworthiness of key mechanical propositions. As these origins were forgotten, the disputes became reinterpreted (particularly by the logical positivist school) as rather trivial squabbles over whether forces are 'observable' or not.

3 Newton's laws of motion, third law

The haziness of Newton's third law - 'action = reaction', as it is popularly known - is palpable in its very formulation. The textbooks often add three additional tenets to the claim: (a) All forces arise between pairs of particles. (b) Such forces are directed along the line between them (the forces are 'central'). (c) The strength of these forces depends only upon the spatial separation between the bodies and not, say, upon their relative velocities. One can then demand that if *a* exerts a specific force *f* upon *b*, then *b* will exert a reciprocating force upon *a* equal in magnitude to *f*, but reversed in direction. Although Newton's own law of gravitation suits these requirements, it is doubtful that he would have accepted the (a)-(c) supplements. Requirement (c) stands in apparent conflict with most frictional forces because their strength depends upon the rate that bodies slip past one another. Requirement (b) seems incompatible with *shearing forces*, which arise when, for example, one layer of water slips over another. Each layer exerts a retarding force upon the other, but these forces point along the layers' interface, not 'the line between them'.

The main motivation for including requirements (a)-(c) is that, on this approach, they are needed to prove

fundamental tenets such as the conservation of energy. For example, (c) justifies the notion of ‘potential energy’. Newton was unconcerned with these requirements because he had no notion that energy conservation holds. Indeed, he often understood the third law in a variant ‘inertial force’ manner.

Consider the sun and its planets. On the (a)-(c) interpretation, ‘action = reaction’ requires that each planet should exert a gravitational force upon the sun equal in strength to the solar gravitational pull that it feels. Since the sun is more massive than the planets, these planetary attractions will not accelerate it greatly. It does not lead to great mathematical error if the sun is treated as if it is the source of an *unreciprocated* force - that is, the solar attractions are described as dependent only upon the planet’s position within an inertial frame. On the (a)-(c) reading, this treatment is only a useful fiction - the reciprocating pulls of the planets must dislodge the sun slightly from its assumed inertial motion. Disregarding the sun’s minor wobblings allows the problem of planetary movements to be *effaced* from the complications of solar motion. When third law requirements can be overlooked in this manner, the force is called *external*; otherwise, they are dubbed *internal*.

However, a long tradition exists of regarding some external forces as nonapproximate in origin. How does a mechanical system balance such a force? Answer: it develops an ‘inertial force of resistance’ - its parts accelerate in such a manner that the sum over all particles of mass *times* acceleration exactly matches the external force. Most modern texts dismiss this approach to the third law as a mistake: no force should be regarded as truly external and inertial reactions do not qualify as forces at all. Indeed, the ‘inertial force’ reading seems merely to repeat the content of the second law over again.

The ‘inertial force’ understanding of the third law becomes more natural within the constraint-based approach of §5, where central forces drop from view. In the mechanics of continua (§6), the ‘principle of material frame indifference’ reveals some further affinities between inertial reactions and forces.

4 Point masses and idealization

Our discussion has involved much hazy talk of ‘particles’; what kind of object is intended by this term? On the interpretation presented so far, a ‘particle’ needs to be a *point mass*: a movable point carrying a fixed mass (and possibly other quantities such as charge). Forces have been required to ‘act along the line between particles’; this makes obvious sense only if ‘particles’ lie at uniquely defined points. Point masses must always remain separate, for the possibility of fusing would permit an infinite source of potential energy. On a point mass interpretation, all forces are of *action-at-a-distance* type, for they originate in one particle, yet act, across an intervening vacuum, somewhere else. *Contact forces*, where one body exerts a pressure immediately upon another through geometrical contact, are not tolerated on this approach to Newton’s laws.

The point mass approach, standard in most modern textbooks, was first proposed by R.J. Boscovich in 1763. Boscovich’s suggestion was rarely embraced during the heyday of classical mechanics. Most practitioners felt that their subject should deal directly with some variety of extended body, and not regard them merely as swarms of points. Newton, although often interested in arguing that objects in apparent contact were actually separated (see his discussion of ‘Newton’s rings’), also believed that atoms possessed hard cores of a certain size.

The point mass presentation of classical physics has gained great favour in modern textbooks partially because of a natural association between its mathematical structures and those of elementary quantum mechanics. ‘Correspondence rules’ exist to convert point mass equations to the partial differential equations of quantum theory. Under this transition, the quantum particles gain a surrogate for ‘size’ due to considerations peculiar to the newer theory, for instance, the exclusion principle. Many authors have been misled by such mathematical relationships into presuming that remarkable successes of classical physics in treating the large-scale phenomena of ordinary life can easily be explained by the way in which point mass theory ‘reduced’ to quantum theory. This impression is misleading, because the point mass interpretation at best provides an awkward basis for setting up the successful models of fluids and elastic bodies that are more adequately established following the programme of §6.

Sometimes it is clearly useful to treat extended bodies *as if* they were point particles. The *locus classicus* of this technique is Newton’s observation that a rigid, perfectly spherical planet behaves gravitationally from its exterior as if it were a single point carrying the same mass. The orbit of a planet can then be calculated without worrying about its interior. Real planets, of course, are neither perfect globes nor rigid and the predictions of point mass

celestial mechanics are slightly inaccurate as a result. None the less, this approximate effacement of the gross behaviour of the planets from their internal complications has inspired a popular ‘as if’ reading of Newton’s laws: they delineate a range of *idealized models* that suit real life situations to a tolerable degree. When greater accuracy is desired, one shifts to modelling the planet as a large swarm of point masses. Each finer scale of idealized modelling provides predictions of increased accuracy, but we should never pretend that our constructions supply anything other than simplified portraits of reality (see Idealizations; Models §3).

On this approach, it becomes difficult to see how Newton’s laws could be shown *false*; at best, they might prove an *inconvenient* series of approximations to utilize. An important distinction should be drawn here: in *any* scientific theory, the successful treatment of everyday phenomena will require artificial simplification because the mathematics pertinent to a fully realistic approach is horrendously complex. But the ‘idealization’ thesis maintains that, quite apart from mathematical intractability, science must study simplified models because of an inherent lack of reality within the very fabric of physics. However, the ‘lack of reality’ in point masses may merely demonstrate that they do not provide the best foundation for a satisfactory classical mechanics.

5 Constraints and rigid bodies

A universe of point masses seems a far cry from standard stereotypes of classical mechanics: is not the subject supposed to treat the universe as a ‘great clock’? Are not clocks composed of gears, rods and springs - extended bodies all? There is a variant tradition, stretching back to antiquity, that exploits the properties of *rigid bodies* in a direct geometrical way (gears and rods, but not springs, are rigid bodies). Typically, such bodies interact with another through contact along their boundaries: two gears intermesh; a bead slides along a wire; a wheel rolls along a plane. These linkages are specified by so-called *constraints*: equations that geometrically link the movements of distinct bodies. The presence of constraints clearly modifies Newtonian behaviour in various ways. For example, the bead will, if no external forces act against it, slide along the wire at a constant velocity forever (if the wire itself is not accelerated). Constraints alter Newton’s law of inertia from ‘travels with constant rectilinear velocity’ to ‘travels at an unchanging speed along the curvilinear constraint of the wire’. Principles of unhampered motion that are adapted to accommodate constraints are called *generalized laws of inertia*.

The existence of constraints, strictly speaking, is incompatible with the point mass reading. Let the bead slide past point *p* upon the wire. What *force* will the wire near *p* exert upon the bead as it slides past? ‘Easy’, the stock reply goes, ‘compute the acceleration *a* needed to move the bead past *p*. Divide *a* by the mass of the bead to obtain the force exerted by the wire.’ But let the bead slide past *p* with a greater velocity. The wire must generate a greater force to hold the bead in its rightful place at *p*. In short, the wire must be able to ‘see’ the bead’s *velocity* before the force needed to maintain the constraint can be exerted. But the point mass understanding of the third law requires that forces be velocity independent; otherwise, conservation of energy might fail.

What should be done? Either constraints are regarded as convenient approximations to point mass reality or our fundamental principles must be modified to tolerate them. In most texts, constraints are introduced in so cavalier a fashion that the policy followed cannot be determined. On the first strategy, ‘rigid bodies’ are simply collections of particles welded together by very strong (but finite) forces. The masses within our wire must shift slightly when a faster bead passes, although these movements may be quite microscopic.

In 1788, however, J.L. Lagrange articulated a version of mechanics that incorporates genuine constraints and rigid bodies within its foundations. He based his approach upon the law of virtual work (sometimes: virtual velocity) and d’Alembert’s principle. The idea behind virtual work is illustrated nicely by the behaviour of a lever. Work can be done if weights are allowed to drop - falling water drives old-fashioned grist mills. String a series of masses along a lever arm; the rigidity of the arm links these weights together by a constraint. How must these weights be arranged if the lever is to stay in *equilibrium* (= at rest)? Answer: any work that might be gained if the weights on one side of the arm are allowed to *fall* must be expended to *raise* the weights strung along the other side. ‘Virtual work’ declares that equilibrium within any constrained set of mechanical parts will obtain just in case their hypothetical abilities to perform work cancel out in the manner described. Laws of this variety (which predate Lagrange) are called *variational principles* because a system’s actual behaviour (equilibrium, in this case) is adduced from a comparison of hypothetical behaviour (that is, imaginary movements given to the weights). For systems not at rest, Lagrange appealed to d’Alembert’s principle. This doctrine claims that if unbalanced external forces are applied to a mechanical system, it will display inertial reactions that exactly balance the external set.

Recall (from §3) that an 'inertial reaction' is simply the acceleration of a body multiplied by its mass. D'Alembert's principle thus maintains that the system 'reacts' to external 'activity' by moving against the activity. We noted that Newton's third law is sometimes interpreted in this manner.

Classical mechanics is often presented using other forms of variational technique, for example, Hamilton's principle and other varieties of 'least action'. Although elementary textbooks often allege that such variants are equivalent to one another and to Newton's original set of laws, this is not true unless a number of background assumptions are made. Hamilton's treatment, especially, renders salient some important features of energy conserving systems, considered with respect to the so-called 'Hamiltonian flow within phase space'. But these matters must be left to standard texts.

Notice that, in dealing with the force upon the bead, we calculated in a direction reverse to what might seem the expected one. In celestial calculations, we compute the acceleration of the earth from a prior knowledge of the *forces* that apply to it. Newton's law of gravitation is the specific force law employed here. But in the bead case, we did not work with any specific force law; instead, the force was calculated merely from the *acceleration* that the wire requires of the bead. Forces induced by the satisfaction of constraints are traditionally called 'forces of reaction'.

Lagrange's approach tolerates both 'forces of reaction' and law specified forces, where the latter are of action-at-a-distance type. It had long been the hope of mechanics, in its 'clockwork' inspired moods, that action-at-a-distance effects might turn out to be the result of contact movements within a hidden medium linking the distant bodies. Descartes and Leibniz believed that the attraction of planets resulted from swimming in a common 'sea' that pushed them together. Appeal to action-at-a-distance forces was considered a retreat to the 'occult' qualities of medieval times. In the nineteenth century, J.C. Maxwell suggested that electromagnetic effects might be communicated between distant bodies through a complicated set of intervening mechanical parts (see Electrodynamics). Such proposals led H. Hertz to reformulate mechanics based upon constraints alone (a wider range of these is needed than appear in standard Lagrangian practice). Hertz (1894) replaced Newton's laws by a simple principle of 'generalized inertia' and identified all forms of energy with actual energy of movement (kinetic energy). Most importantly, the notion of force is essentially discarded in Hertz's system, since only the derivative 'forces of reaction' are tolerated in his framework. Hertz's system provides the best realization of the philosophical dream of a truly machine-inspired mechanics. Interest in Hertz's project faded with the rise of quantum theory, but its distrust of the Newtonian notion of 'force' has proved longer lived. In the author's opinion, 'force' should occasion no unhappiness as long as mechanics remains faithful to a point mass interpretation; it is the frequent appeal to *post hoc* 'forces of reaction' that generates the uneasy sense that 'force' functions as an unnecessary ingredient within mechanics.

In any case, the notion that the universe could actually move as one great *machine* is less plausible than one might expect. Machines are designed (insofar as possible) so that their parts slip over each other without binding. If a collection of rigid parts is randomly assembled, without the guidance of a designer, they are likely to end in *overconstraint*: the expected conditions of sliding, rolling, and so on, among its parts cannot be satisfied all at once. To accommodate the overconstraint, some of the parts will need to distort or fracture, thus losing their postulated rigidity.

In other words, once the basic 'particles' of mechanics are granted any spatial extension at all, they are likely to lose their postulated rigidity at some time or another. How does this eventuality affect Lagrange's programme for the foundations of mechanics? A retreat to an 'idealization' defence is possible: mechanics tries to idealize real physical systems in terms of constrained rigid bodies, despite their lack of permanent reality. Some advantage over point mass idealization is gained, for a better set of modelling tools has been assembled. It would be preferable however, if an approach to mechanics could be found that accepts bodies which are capable of distortion at all levels of analysis. The materials in this reformulated mechanics should be truly flexible entities, such as springs and fluids, which can smoothly distort or flow when the right external pressures are exerted. Such objects are called 'material fields' or *classical continua*.

6 Continua

If one tries to describe continua directly, one quickly discovers that formulating plausible laws for genuinely

flexible bodies introduces many conceptual problems. All of the problems of the 'infinitely divided' that have plagued philosophy and mathematics since the time of Zeno's paradoxes arise (see Zeno of Elea). Mechanics supplements these with some peculiar difficulties of its own.

For example, it seems natural to interpret the term 'particle' in Newton's laws as an 'infinitesimal portion of a continuous body'. If such a 'particle' belongs to a macroscopic body that stretches, must not that 'particle' enlarge infinitesimally under the stretching as well? But how can a point *p* sensibly expand to become a 'bigger point'? And what should ' $F = ma$' require of *p*? If *p* enlarges under an applied force, should its 'mass' (or, more properly, its density) also alter? Traditional arguments concerning 'infinitesimals' were plagued by vagueness of this sort, as critics such as Bishop Berkeley swiftly observed (see Berkeley, G. §§8, 11). Leibniz's celebrated philosophy of 'monads' represented, in part, a sophisticated attempt to surmount some of these problems by moving outside of the arena of space and time altogether (see Leibniz, G.W. §4).

Although infinitesimal readings of Newton's second law are common in textbooks, the considered modern opinion holds that this is a mistake: ' $F = ma$' should apply only to the *extended* parts of a continuous body. This shift in perspective introduces many unexpected conceptual subtleties. Suppose that A is a continuous body with external forces applied at various spots along its outer edge and within its interior. If A is a perfectly *rigid* substance, all of these forces can be added together as if they act at a common location. In a rigid body, a force applied at *p* can be shifted to any other position *q* and still pull A equally to the right. Applying a force at *p* rather than *q* affects only how A will *rotate*, not how it *translates*. Indeed, by defining the so-called 'moment' of A's array of forces (roughly, a measure of their 'off-centredness'), Euler showed how A's rotation could be calculated (the principle employed is called 'balance of angular momentum' or 'moment of momentum'). Euler's two principles - non-infinitesimal ' $F = ma$' and 'moment of momentum' - completely settle how any rigid body will respond to applied forces.

But the success of these principles appears to trade upon A's postulated rigidity. If A is composed of flexible stuff, then how it reacts to a schedule of applied forces will clearly reflect the materials of which it is made - the same set of forces will move rubber and water in completely different fashions. To make further progress, we must consider the *contact forces* that arise upon the surfaces inside A that separate points *p* and *q*. Draw an imaginary boundary shell B around *q* that excludes *p*. An external force applied at *p* can transmit an indirect influence to *q* if it successively alters the conditions of the shells of matter that surround *q*. As the matter outside of B changes its state, a new set of forces will be applied against the *surface* of B *by direct contact*. These 'contact forces' will work their way successively through the shells surrounding *q* and eventually affect *q* itself. The mathematical characteristics of such 'contact forces' are rather different from those of the action-at-a-distance types considered previously.

In the 1820s, Cauchy showed how these two types of force could be harmonized in a fashion that supplies an adequate foundation for continuum mechanics. He first assumed that ' $F = ma$' holds for (almost) every shell B enclosing *q*. '*F*' represents the resultant of summing the contact forces around B, supplemented by whatever external forces operate within B's interior. ' $F = ma$' then assigns an overall 'acceleration' to B. Unfortunately, these observations still allow individual *points* inside B to move in any of the variety of ways that are consistent with the *averaged* acceleration that noninfinitesimal ' $F = ma$' assigns to B. But a framework of laws is not adequate to continua until the principles that govern *point* motion within a flexible body are articulated. At this juncture, Cauchy (1823) had the brilliant insight that, as the volume of B shrinks to 0, Euler's two principles ensure that a rather abstract assemblage of numbers, called the *stress tensor*, needs to be defined at each point *q*. Cauchy's 'stress' turns out to be the novel ingredient that renders the mechanics of continua quite distinct from the other formulations of classical physics we have considered. Popular books often encourage the impression that 'stress' is merely a synonym for 'force', but Cauchy's tensor actually supplies an abstract replacement for the naïve idea that a 'point' like *q* might possess an 'infinitesimal surface' upon which the surrounding materials can tug and shear in different directions. In other words, 'stress' provides a subtle means of avoiding the paradoxical 'points with surfaces' that conceptually bedevilled earlier attempts to discuss continua.

With Cauchy's new notion in hand, the differences between water and rubber can be traced to the distinct manners in which states of stress affect stretching within the materials. The law of stretching for rubber - its so-called 'constitutive equation' - looks quite different from the law suitable for water. Such 'constitutive principles'

together with Euler's two laws form the core of doctrine upon which continuum mechanics rests.

Cauchy's direct approach to continua usually provides a more reliable guide to the behaviour of real life materials than modelling them as arrays of classical points or rigid bodies. Some of the nineteenth-century hostility to 'molecules' stemmed from a recognition of this empirical superiority (the historical dispute over the so-called 'rariconstant' theory of elasticity was a case in point). But Cauchy's programme is complicated, and, without sufficient care, one can quickly return to conceptual absurdities such as 'points with infinitesimal surfaces'. Many modern texts treat continua as large swarms of point masses simply because this approach provides a 'quick and dirty' way of getting some key classical models up and running, without needing to worry about delicate foundational considerations. Handy appeals to the necessity of 'idealization' camouflage some otherwise awkward *non sequiturs*. But if one hopes to appreciate the conceptual issues with which a Leibniz would have struggled, the difficulties of continua need to be addressed more honestly.

In point of historical record, a variant programme for approaching continua based upon 'strain energy' rather than 'stress' was pursued in the late nineteenth century by the so-called 'energetic school'. See Harman (1982) for further details.

7 Retrospect

Which of these approaches to mechanics should the scientists of the nineteenth century have favoured? On the one hand, they had little doubt that the apparent continua of real life - strings, fluids, and so on - are lumpish in composition, possibly suggesting the suitability of rigid bodies as the basic objects of physics. But such molecules also seemed to be capable of vibration, indicating that the molecular 'lumps' might possibly act as flexible bodies at a microscopic level of analysis (the 'ether' that was thought to surround the molecules also acted like a continuum). Such uncertainties spawned lively arguments over the proper basis of classical mechanics, disputes that were never resolved simply because Nature decided to turn quantum mechanical at just the point where experiments might have settled matters.

Unfortunately, many popular accounts of the history of science and philosophy often forget these genuine conceptual worries and presume that 'classical mechanics' is correctly interpreted only from a point mass stance. The many philosophers and scientists who struggled to articulate variant conceptions are frequently dismissed as incompetents blind to the true mechanical light. But the deep philosophical heritage of classical mechanics is better appreciated if its basic internal tensions are more sympathetically understood.

Medical ethics

Medical ethics was once concerned with the professional obligations of physicians, spelled out in codes of conduct such as the ancient Hippocratic oath and elaborated by contemporary professional societies. Today this subject is a broad, loosely defined collection of issues of morality and justice in health, health care and related fields. The term 'bioethics' is often used interchangeably, though it is also used with its original broad meaning, which included issues in ecology.

The range of concerns grouped under 'medical ethics' begins with the relationship of doctor to patient, including such issues as consent to treatment, truth-telling, paternalism, confidentiality and the duty to treat. Particular moral uncertainty is engendered by contexts which demand divided allegiances of physicians, such as medical experimentation on human subjects, public health emergencies and for-profit medicine. Issues in medical ethics arise in every stage of life, from the fate of defective newborns to the withholding of life-sustaining therapies from the very old. Medical practices with patients who may not be competent to make their own medical decisions, including paediatrics and psychiatry, raise a distinctive set of ethical issues, as does medical genetics, which involves choices affecting family members, future individuals and offspring in utero. *In recent years, medical ethics has broadened its focus beyond the individual physician or nurse to include the organization, operation and financing of the health care system as a whole, including difficult theoretical and practical uncertainties regarding the fair allocation of health care resources.*

Medical ethics is at once a field of scholarship and a reform movement. The latter has campaigned in many countries on behalf of patients' rights, better care of the dying and freedom for women in reproductive decisions. As a field of scholarship, medical ethics addresses these and many other issues, but is not defined by positions taken on any of them. Though ethicists often favour an emphasis on informed consent, oppose paternalism, urge permission to end life-sustaining therapy (or choose suicide) and seek protection of human subjects of experimentation, a diversity of viewpoints finds expression in the medical ethics literature.

1 Development of medical ethics

Medical ethics, in the narrow sense of codes of professional conduct for physicians, has a history dating back to the Hippocratic oath of the fourth century BC (see Hippocratic medicine). But medical ethics became a broad field of scholarship only after the Second World War. The terrible experiments carried out by Nazi scientists on nonconsenting human subjects were publicized and judged at the Nuremberg trials, alerting researchers and the public to the potential for abuse in clinical investigations. This lesson was learned anew in the two decades which followed as reports emerged in the United Kingdom and the United States of wrongs done to patients in the name of science, such as the injection of live cancer cells into unsuspecting patients, and the deliberate infection of institutionalized children with hepatitis. These and other abuses were detailed by the investigators in articles published in leading research journals.

Public attention was drawn to medical ethics, at least in the United States, by the moral dilemmas faced by the world's first kidney dialysis service, which had to choose which of many patients needing treatment would be permitted to live. The dialysis service, at Swedish Hospital in Seattle, created a committee in 1962 to ponder the patients' dossiers and to 'play God' in deciding who was most deserving (the winning candidates were often patients who most resembled the committee members). Even more widely discussed, a decade later, was the fate of Karen Quinlan, a young woman who had fallen into vegetative state. Her family sought permission from the courts to remove her from life-sustaining therapy, exercising a 'right to die'. A series of cases during this period involving the termination of treatment of defective newborns led not only to public debate but to stringent government guidelines for treatment, including, at one point, a national telephone number for reporting suspected doctors. Debates over doctors as agents of death intensified in many countries in the wake of increasingly liberal euthanasia policies in the Netherlands during the 1990s.

The public's fascination with medical ethics, which has increased year by year for over two decades, stems both from advances in medicine and from social changes which affect attitudes towards medical practice (see Technology and ethics §3). Each new drug, device or technique, from the dialysis machine to genetically-engineered human growth hormone, necessitates a decision on its use. Media reports of these advances

have come to include, as a matter of routine, some discussion of attendant ethical issues. A recent example is that of Dolly the sheep, cloned from a cell in another sheep's udder; global reportage of this case prompted ethical questions about the potential use of cloning techniques on humans. Just as important, however, have been issues arising from the reconsideration of traditional medical practices in light of changes in social attitudes. The turbulent 1960s, which gave rise to 'liberation' movements on behalf of many marginalized groups, led to a reconsideration of traditional physician authority, including prerogatives to withhold information and to decide the course of treatment. Thus a variety of traditional medical practices, ranging from choice of which women could be candidates for artificial insemination to the use of charity patients for medical experimentation, became targets of protest and subjects of debate.

The agenda for medical ethics has thus been determined by events outside the discipline itself rather than by its own path of intellectual progress. Anthologies and textbooks require frequent new editions, adding some topics and dropping others, tracking the course of new developments in medicine and the interests of the public. Medical ethics is thus a field of scholarship in public service. It is simultaneously a field of practice. Ethicists, those who are credited with expert knowledge of medical ethics, serve on the staffs of hospitals, in medical research institutes, and as staff members of public agencies (see Moral expertise). A Society for Bioethics Consultation has functioned for many years in the United States, and ethics institutes in the Netherlands and elsewhere in Europe have been likewise composed of philosophers and others who provide ethical advice on a professional basis. National bioethics commissions in over twenty countries offer opinions on issues ranging from the definition of death to the rationing of health care resources (see Death §§1, 3). Medical ethics has become a global concern, and is debated in such bodies as UNESCO's International Bioethics Committee and the International Association of Bioethics, as well as regional groups in Europe, East Asia and South America.

Though the boundaries of the field of medical ethics are vague and shifting, a number of subjects form a recognizable core. Prominent among these are ethical issues arising in reproduction, genetics and death and dying (see Genetics and ethics; Reproduction and ethics; Life and death). Another central issue is the relationship between doctor and patient.

2 The doctor-patient relationship

In traditional medical ethics, the doctor held the reins of authority. The medical mission was to improve or protect the health of the patient. The doctor might accomplish this by giving patients the unvarnished truth, respecting their desire for confidentiality, and pointing out alternative courses of treatment. But if doctors judged these to stand in the way of health, their obligation might be to shade or withhold the truth, share information about patients with others, and manipulate patients into accepting their preferred mode of treatment.

Changes in social attitudes in English-speaking countries have brought demands for a relationship of doctor and patient based instead on respect for the patient's own wishes. This is understood to require the doctor to be entirely candid about the patient's condition, to disclose the full range of alternative therapies, with an account of their benefits and risks, and to share information about the patient with others only when given express permission by the patient.

Much of the early writing in medical ethics in the UK and US was devoted to supporting these new expectations, and self-determination has replaced paternalism as the organizing principle of medicine (see Paternalism). Traditionalist understandings of the doctor-patient relationship persist in other parts of the world, such as Asia and Latin America, where the Anglo-American insistence on self-determination in such matters as disclosure in the diagnosis of fatal illness is regarded as heartless and irresponsible, robbing the patient of hope.

In the older literature of medical ethics, which was chiefly concerned with the duties of the professional as such, rules on such unprofessional practices as fee-splitting, self-referral, and kickbacks played a prominent role in specifying the requirement of fidelity to the patient's interest (see Professional ethics). These issues were replaced at centre stage by the more dramatic questions of life and death which made medical ethics of great interest to the public. However, they have returned to prominence in recent years as innovations in health care financing have deliberately placed physicians, in some countries, in positions of potential conflict of interest in order to motivate them to limit the cost of care. In the United States, 'managed care' organizations often make the conflict explicit, withholding part of the doctor's pay if the latter has failed to be sufficiently frugal in ordering high-cost services

for patients. Critics point to these arrangements as an abandonment of professionalism and a blow to patients' trust of doctors, while proponents point to the doctors' very professionalism as a safeguard against the temptation to exploit the patients' lack of medical knowledge when withholding needed care.

3 Human experimentation

Abuses of human subjects of medical experimentation, most notorious in Nazi medicine but now known to have been practised elsewhere, notably by Japanese physicians acting in occupied China, seem to have abated since the Second World War. Nevertheless, ethical dilemmas persist and have been a continuing concern of scholars and practitioners in medical ethics. The basic norms of humane research have been enforced in the UK and US for some decades and, as with clinical medicine, are founded on the two principles of physician concern for the patient and on patient self-determination, secured in large part through informed consent (see Consent). The former, however, is diluted inevitably by the physician-scientist's concern for future patients, who will receive no benefits unless the experiment is successful in scientific terms.

The potential conflict between the roles of therapist and scientist arises in many randomized clinical trials (RCTs), which is especially troublesome because the RCT has emerged as the gold standard of evidence of clinical efficacy. Patients recruited to RCTs are typically told that the investigators do not know which arm of the trial (for example, a drug or a placebo) is most beneficial. Even if this is true at the beginning of the study, however, RCTs typically enrol patients over a period of months or years, and later recruits may not be informed of trends in accumulating (if inconclusive) data which might lead a clinician to favour one treatment or the other rather than flipping a coin. The conflict in roles between healer and scientist remains.

4 Ethical issues in psychiatry, paediatrics and geriatrics

The currently favoured model of the doctor-patient relationship centres on the doctor's duties of care and advocacy for the patient and the patient's right of self-determination. The latter, however, assumes that patients are competent to make their own decisions. Physicians in psychiatry, paediatrics and geriatrics deal with patients whose decision-making capacities are sometimes lacking, and with others whose mental competence fluctuates over time.

No satisfactory substitute for full decision-making competence has yet been devised, but several strategies are used. For decisions at the end of life, particularly those which need to be made when they are debilitated by illness or are in vegetative state, some patients have executed 'living wills' setting out instructions for their care and have given trusted intimates 'durable power of attorney' to make decisions on their behalf. Unfortunately, these instruments have not proved effective: surveys have shown that physicians tend to overlook them and permit family members to override them. For mental patients, the so-called 'Ulysses Contract' (recalling the island of the Sirens) would permit the patient to waive, in advance, rights to refuse sedation and other treatment in the event of temporary loss of full competence, as in a manic episode. All these strategies require an earlier period of mental competence in which the instruments are created, which makes them inapplicable to paediatric cases. In the latter, and often in psychiatric and geriatric cases as well, the physician must instead rely on others to decide on the patient's behalf or else rely on the decisions of a marginally competent patient. Since self-determination is valuable at least in part because of the protection it affords to the (competent) patient, this last strategy is sometimes self-defeating, though it may be the least unsatisfactory alternative.

5 Allocation of health care resources

The central ethical issues in allocation of health care resources - who should receive what kinds of care, and who should pay for it - are questions of distributive justice (see Justice §2). Though the texts which sparked the revival of philosophical work in distributive justice, particularly Rawls' *A Theory of Justice* (1971), made little mention of health care, attempts to extend the philosophical work to the arena of health were not long in coming. These works addressed a series of questions of both philosophical interest and practical importance. Should health care be distributed in any distinctive way, different from other goods and services? Does it have any particular priority? Is there a floor or a limit on the share of social resources which should be devoted to health care? How equal should provision of health care be, and on what basis should scarce health care goods and services be allocated? What role should markets play in determining health care allocations, and what role democratic political choice?

In the United States, there is considerable debate among philosophers and the public alike on whether a society which fails to guarantee at least a basic level of health care benefits can be called just (in other industrialized countries, this is not questioned seriously). Even where basic health services are available to all, debate exists over the degree to which the remainder of health services ought to be delivered on an egalitarian footing, and over what kinds of allocations qualify as egalitarian.

Under the heading of ‘prioritization’, philosophers have addressed the issues involved in rationing decisions by government authorities, bedside clinicians, and private insurers alike. Ought the goal of rationing be to maximize health, understood as the greatest total number of years of life of all patients affected, discounted by remaining deficits in health? Or should the sickest patients, or those with the most urgent needs, be given priority? Should large gains in health take priority over smaller ones, even if the total gain in health, within a given budget, is achievable in a given instance by the aggregation of the smaller gains? Should the rationing agent consider the self-interest of each patient alone, or should the wishes of third parties (including family members, members of a risk pool, and, most generally, empathic fellow-citizens) also be taken into account?

Health policy has come to rely on the ‘Quality-Adjusted Life Year’ and other measures of the success of health care, but deep divisions over their implications persist in medical ethics. A commitment to maximizing QALYs, for example, tends (*ceteris paribus*) to choose the younger patient over the older, which strikes some theorists as proper but others as arbitrary or discriminatory.

Rationing decisions have been made in the past through a combination of means, including physician discretion, budget allocation and private purchasing in markets. The principles upon which allocation has been based have rarely been explicit. Though little consensus exists in medical ethics over the resolution of these controversies, the rising costs of health care prompt demands for allocation decisions which are principled, public and democratic. A very ambitious attempt to honour these demands, conducted by an agency of the state of Oregon, in the United States, has been scrutinized by health authorities around the globe, and several have initiated smaller-scale initiatives to the same end.

More broadly still, medical ethics has begun to address health-related issues which transcend health care. Enduring differences in health status according to class and race, even in countries such as the UK which provide good health care to all citizens, prompt questions of social justice about other determinants of health. These inquiries are particularly important in consideration of medical ethics in developing countries (see Development ethics).

6 Theory and methodology

With one foot in the academy and the other planted in the ‘real worlds’ of clinical medicine and health policy debate, medical ethics is, of necessity, an untidy discipline. The contexts in which ethicists perform their duties, be they an intensive care ward or a public agency, often preclude elaborate philosophical argumentation. Medical ethicists, moreover, are a varied lot. There is no credential nor any single disciplinary background: philosophers share the title with theologians, lawyers, physicians, social scientists and anyone else who claims it.

It is therefore not surprising that medical ethics lacks theories and a standard methodology. Though contributors to the subject may be informed by the traditions of moral thought, some writing, for example, as utilitarians, others as Kantians, and others as Roman Catholic moral theologians, there is no approach which any appreciable plurality share. The most widely-noted theoretical framework for medical ethics specifies a set of *prima facie* duties for health care professionals (Beauchamp and Childress 1979; Gillon and Lloyd 1994). These principles, however, must be weighted and applied in context by the decision-maker, and in the view of critics fall short of a comprehensive theory. In practice, ethicists approach a clinical case or a public policy issue more or less as anyone else would, except in being conversant with a literature which makes important distinctions, advances and criticizes leading lines of arguments, and dwells in rarefied abstraction. Ethicists begin with no standard set of assumptions, and do not necessarily converge in their conclusions.

What intellectual authority, then, does medical ethics bring to bear on ethical dilemmas in health care? Perhaps none; but this is not where its promise and its value lie in any case. Medical ethics is but one small part of the conversation of humankind, but it is, at its best, of particular interest. It is a formal and considered response to a remarkable challenge from within and without the profession of medicine to debate - publicly, impersonally and prospectively - whether medical practices are right and just. Its theoretical and methodological anarchy

notwithstanding, this is an endeavour which can be commended to other arenas of public life.

Medicine, philosophy of

The philosophy of medicine can be generally defined as encompassing those issues in epistemology, axiology, logic, methodology and metaphysics generated by or related to medicine. Issues have frequently focused on the nature of the practice of medicine, on concepts of health and disease, and on understanding the kind of knowledge that physicians employ in diagnosing and treating patients.

The history of philosophical reflections concerning medicine reaches back to ancient Greece. Medical knowledge took a further step in the nineteenth century with the introduction of clinical pathological correlations, statistical methods, and systematic experimentation, out of which grew substantive literature exploring the character of medical reasoning and the framing of diagnoses. Debates also developed over contrasting physiological, ontological, nominalist and realist accounts of disease entities.

Contemporary philosophy of medicine has been concerned with the nature of medicine in an increasingly scientific context, a concern that has generated several models of medicine, including George Engel's biopsychosocial model, as well as analyses of the nature of the physician-patient interaction. The longstanding debate over the ontological status of health and disease has been recapitulated and extended by a number of authors, favouring an objective, statistically-based account, while others argue for an irreducible social and valuational element in these concepts. Several approaches to diagnostic logic, including Bayesian and computer-based analyses, have been developed, and sophisticated methods of determining disease causation and therapeutic efficacy, including analyses of the randomized clinical trial, have also been explored. Whether the philosophy of medicine is a distinct discipline or a branch of the philosophy of science has provoked vigorous arguments.

1 Definition and scope

The philosophy of medicine can be generally defined as encompassing those issues in epistemology, axiology, logic, methodology and metaphysics generated by or related to medicine. Though medical ethics is a component of the philosophy of medicine in its broadest conception, this article will not attempt to cover that discipline, except at a few critical points. Medicine is the art or science of restoring or preserving health, and may involve drugs, surgical operations, or other types of intervention. Though medicine has an extensive and continually increasing scientific basis, several physician-philosophers, including Otto Guttentag and Edmund Pellegrino, have seen the essence of medicine in its orientation to one distinct end - the affirmative response of the physician to a plea from the individual patient to help in restoring or preserving that patient's health. Issues in the philosophy of medicine have thus focused on the concept of health (and that of disease), and on understanding the kind of knowledge that physicians employ in diagnosing, treating and caring for patients. These issues have an extensive historical pedigree.

2 History of the philosophy of medicine

There is a rich, complex history of philosophical reflections concerning medicine reaching back to the beginnings of Greek philosophy (see Hellenistic medical epistemology). These can retrospectively be recognized as part of the 'philosophy of medicine', though it was not until the nineteenth century that that expression (and 'medical logic') gained currency. By involving a significant self-critical appreciation of the difficulties in medical knowing, the philosophy of medicine contrasts with various speculative, non-empirical or only quasi-empirical, reflections on the etiology, pathogenesis and cure of disease that have been undertaken in all cultures. An explicit concern with the status of medical theories and medical claims is already present in the Hippocratic corpus (see Hippocratic medicine). The *Precepts*, for example, offers an account of medical theory as a composite memory derived from sense perception; the author underscores the importance of relating medical theorizing to actual experience, thus reflecting a philosophy from the period.

From the time of the Hippocratic corpus into the nineteenth century, mainstream medicine offers an intertwining of speculative and empirical attempts to discover the true nature of disease and proper treatment, set against the background of occasional assessments of medical knowledge. Such intertwinings are found in the work of Galen (129-*c*.210), who underscores the importance of observation and experiment. One finds them as well in René Descartes' attempts to determine the fundamental laws of metaphysics, physics and medicine, especially in the

Treatise on Man (1662) (see Descartes, R. §2). The theoretical disputes of the seventeenth and eighteenth centuries between those using chemistry and those using mechanics, as the basis for theory and practice, were as much speculative as empirical, as were the debates about the nature of life and the status of medical systems. Often physicians who engaged in speculative, largely non-empirical, reflections on medicine, and also attempted to construct medical systems, had significant influence on the practice of medicine. On the other hand, one of the system builders, John Brown (1735-88), attracted the attention of contemporary philosophers such as Kant and Hegel.

In response to the uncritical incorporation of speculative reflections and theorizing into medical theory and practice, Thomas Sydenham (1624-89), the practice partner of John Locke (1632-1704), attempted to nurture a better appreciation of empirical observation in medicine. Inspired by the work of Sir Francis Bacon, Sydenham engendered a cluster of substantial explorations of method in medicine. This literature developed Sydenham's concern not to allow theoretical presuppositions to distort clinical findings. It produced conceptually attentive assessments of medical nosologies and the status of medical knowledge. Among the contributors were Carl von Linnaeus (1707-78) and François Boissier de Sauvages (1701-67). Reflections on the status of medical knowledge took a further step in the nineteenth century with the introduction of clinical pathological correlations, statistical methods, and systematic experimentation. One subsequent line of analysis came from medical scientists, who criticized previous medical knowledge and set out new claims regarding the status of disease entities. To this debate, François-Joseph-Victor Broussais (1772-1838) contributed a special meaning for the term ontological, using it to identify accounts that regarded diseases as in some sense abstract entities. The debates were complex and involved distinguished contributors, such as the cellular pathologist Rudolf Virchow (1821-1902). They encompassed analyses of etiological factors into necessary and sufficient causes. In these debates, distinctions were drawn between physiological and ontological accounts of disease, at times distinguishing physiological and anatomical explanations of disease, and at times nominalist and realist accounts of disease entities. This debate brought together long-standing concerns as to whether 'disease' identified a thing in the world (that is, a disease entity, an *ens morbi*), a recurring constellation of clinical findings, a set of causal factors, or was a term that conventionally identified particular findings.

The changes in medicine during the nineteenth century provoked further assessments of medical knowledge and method. Initially, this produced a mixture of the philosophy of medicine as a specialized speculative philosophy of nature and the philosophy of medicine as an assessment of scientific method in medicine. For example, Blane's *Medical Logick* (1819) incorporated both an enumeration of ten elementary principles of life, as well as a study of fallacies in medical reasoning (including Bartlett's *Philosophy of Medicine* (1844)). By mid-century, this literature compassed a sophisticated appreciation of problems in medical investigation, observation and experiment, which placed concerns about medical knowledge in terms of problems of inductions. Out of this grew a substantive literature exploring the character of medical reasoning and the framing of diagnoses. This tradition of disciplined philosophical reflections concerning medicine and medical knowledge continued as interest in bioethics emerged (see Bioethics). This literature includes the contributions of Ludwik Fleck (1979), who in many respects anticipated the work of Thomas Kuhn in the 1960s. As the second half of this century began, the term 'philosophy of medicine' could identify a complex literature of philosophical reflections.

3 Models of medicine

Medicine has been most generally understood as helping the patient with the care of their health. This perspective makes intelligible why medicine was paradoxically characterized by the nineteenth-century pathologist Virchow as a 'social science', and also suggests why, in spite of the extraordinary advances in the application of reductionistic molecular biology in medicine, many endorse George Engel's 'biopsychosocial' model of medicine as a more appropriate vision of the discipline. This model is not antiscientific, but is viewed as a supplement to a narrower 'biomedical' model. The biopsychosocial model involves a recognition of complex causation, emphasizes that how a disease affects any one individual requires consideration of psychological, social and cultural factors, and stresses individual variability of a disease, which ' reflects as much… [psychological, social and cultural factors] as it does quantitative variations in the specific biochemical defect' (Engel 1977: 132). The centrality of the patient has also led the philosophy of medicine to examine the complexities of the physician-patient relationship, and has explored several different models of this interaction. Consensus, at least in the USA, has since 1970 tended away from a more traditional paternalistic approach to the patient and toward an account that emphasizes the moral

importance of the autonomous and informed patient participating in shared decision making with the physician, tempered by the differing perspectives of each of the parties.

4 Concepts of health and disease

There appears to be a general consensus in philosophy of medicine that the debate over the concepts of health and disease has been the main contender for a 'defining problem' of the field of philosophy of medicine. Reflections concerning concepts of disease, illness, malady and health have since the 1950s recapitulated traditional concerns regarding the status of disease entities. They have assessed the extent to which 'disease', 'illness', 'health', 'disability', and so on, identify states of affairs, reflect cultural values, or direct health care interventions. In 1954 Lester King noted how particular values mark states of health from states of disease. Debates concerning the value-laden and theory-laden character of disease and health concepts, as well as medical notions of normality and abnormality, have provoked attempts to justify culture-independent understandings through appeals to the ends of medicine, the essential functions of a being, the formal conditions of freedom or species-typical (statistically-based) levels of species-typical functions. Such approaches offer the promise of a straightforward critique of the use of medicine as a vehicle of political control, as well as a more unified account of disease and health for both humans and animals. Others have argued for the essentially culture- and value-laden character of concepts of health and disease, as well as the instrumental character of disease and illness, diagnosis, prognosis and treatment. In such accounts, concepts such as disease, illness and malady become warrants for medical interventions (Engelhardt 1996). Distinctions between mental and somatic diseases and illnesses have been developed and criticized, background concepts such as that of malady have been explored, and the role of diagnostic taxons in medical decision-making and artificial intelligence approaches to clinical problem solving and diagnosis have been studied, placing concerns with disease and health in terms of larger themes of medical explanation and reasoning. Recent advances in the molecular genetics of various diseases have occasioned several philosophical analyses of normality and genetic disease (Nordenfelt 1995).

5 Logics of diagnosis, prognosis, and therapy evaluation

Investigations into the logics of diagnosis and prognosis began in the 1950s, stimulated by the thesis of Paul Meehl (1954), that prognoses made by simple statistical models bettered prognoses made by clinicians. More explicit logical analyses of the diagnostic process developed in the 1960s and 1970s, employing both Bayesian inference and branching logics. The former approach was articulated and argued for by Ledley and Lusted in an influential article in 1959, and applied by other clinicians during the 1960s in a variety of medical specialties. The Bayesian approach uses Bayes' theorem to revise initial (or 'prior') probabilities in the light of the outcomes of further clinical tests (see Inductive inference §3; Probability, interpretations of §5). The approach can outperform even experienced clinicians, if confined to narrow areas of inquiry, but requires exponentially growing amounts of data in broader or more complex domains. For many test results, this information is not available.

The branching logic approach is represented by a tree-like structure in which each branch point or node is a decision point for the physician, and can have two or more paths leading from it to additional decision nodes. This approach was defended by Alvan Feinstein in several articles in the 1970s, and applied in neurology by Kleinmuntz, and to the diagnosis of acid-base disorders by Bleich. Relics of this approach can still be seen in various diagnostic flow charts in textbooks of medicine. Branching trees can have 'chance' or probabilistic nodes inserted within them that can be subject to Bayesian inference. This type of structure, supplemented with quantitative measures of benefits and harms (utilities), constitutes the still vigorous subject of 'clinical decision analysis'. In spite of a large number of proponents still committed to the decision-theoretic approach, the need to adhere to a strict order of information presentation, and the lack of empirical information about certain key conditional probabilities, led other investigators of the diagnostic process, such as A. Gorry and J. Kassirer, to look toward the developing area of artificial intelligence for a more tractable approach.

Work in artificial intelligence in medicine (AIM) and philosophical commentary on it flourished during the late 1970s and 1980s, resulting in a number of accomplishments, including the INTERNIST-1 diagnostic program, later known as QMR (Quick Medical Record). The QMR program is now marketed for physicians, and used as a teaching tool. AIM research continues to be actively pursued under the more inclusive rubric of 'medical informatics', which has turned its attention beyond diagnostic reasoning to investigate the possibilities of a unified medical language and integrated medical information systems. In spite of the advances made in diagnostic, prognostic and

therapeutic logics, there is at present no consensus that any one approach has fully captured the physician's reasoning process. Inquiry continues, and includes newer approaches such as connectionist systems, case-based reasoning and fuzzy logics.

Philosophical inquiry has also been directed at methods for determining the causes of disease and evaluating therapies. These issues are also addressed under the rubric of 'clinical epidemiology'. An analysis of how a specific agent can be identified as the 'cause' of a disease has its historical roots in Koch's postulates, which articulated a series of necessary and sufficient conditions for a disease's cause within the context of nineteenth-century bacteriology. Twentieth-century discoveries in microbiology have required the generalization of Koch's postulates, and the development of a more complex approach to the identification and confirmation of disease causation (Evans 1976). A protracted debate about the true cause of AIDS, begun by Duesberg in the late 1980s, has been conducted largely within the context of this inquiry. A related question involving causation, how to determine whether a medical intervention has had the effect of ameliorating or curing a disease, has generated an extensive literature (as well as numerous governmental regulations), most frequently in the area of new therapeutic drugs. Philosophers of medicine have participated, along with statisticians and clinicians, in analyses of various research designs, including the soundness, and the ethics, of what is generally acknowledged to be the 'gold standard' of efficacy determination: the randomized controlled clinical trial (Schaffner 1993) (see Medical ethics §3; Statistics and social science).

6 Relation of philosophy of medicine to philosophy of science

Since the inception of the current era of professional inquiry in the philosophy of medicine - inaugurated by the *Philosophy and Medicine Series* in 1975, *The Journal of Medicine and Philosophy* in 1976 and its sister publication *Theoretical Medicine* (née *Metamed*) in 1979 - an ongoing debate has occurred on whether the philosophy of medicine is a distinctive branch or field of philosophy, or whether it is reducible to or replaceable by some combination of philosophy of science (including the philosophy of biology), philosophy of mind and moral philosophy. Critics of the distinctiveness of the discipline, such as J. Shaffer and A. Caplan, have tended to the view that medicine is essentially the science of biology, and philosophy of medicine is (and should be best pursued as) philosophy of science. What is left out can be assigned to the realm of moral philosophy. Caplan elaborates (1992), arguing that philosophy of medicine is not at present a disciplinary 'field'. It is not a field because it is not integrated into its cognate areas of either philosophy or medicine, it has no set of core readings or 'canon', and it has no core problems (with the exception of the controversy about health and disease as reviewed) about which deep intellectual debates rage. Though Caplan does not deny the theoretical possibility of a philosophy of medicine - in fact, he suggests it should be a necessary foundation for bioethics, could have salutary consequences for philosophy of science, and could be important for medicine in its inquiries into clinical trials, computerized diagnosis and modern molecular genetics - he does not think such a discipline as yet exists.

Defenders of the distinctiveness of a discipline of philosophy of medicine, such as Pellegrino and Wulff, have argued that there are many and varied examples of the application of philosophical approaches and methods to medical topics, some of which would appear to fall into just those areas that Caplan urges be pursued. Sometimes these examples may be viewed as instances of philosophy *and* medicine or as philosophy *in* medicine, but these inquiries all share strong similarities with each other and buttress a more distinctive philosophy *of* medicine. The latter term Pellegrino (1976) prefers to reserve for a philosophical investigation of 'the clinical encounter with a human being experiencing health, illness, neurosis, or psychosis, in a setting which involves intervention into his existence'. Others may favour the broader definition of the term 'philosophy of medicine' used in the present article, which would include philosophical inquiries within medicine generally.

Medieval philosophy

Medieval philosophy is the philosophy of Western Europe from about AD 400-1400, roughly the period between the fall of Rome and the Renaissance. Medieval philosophers are the historical successors of the philosophers of antiquity, but they are in fact only tenuously connected with them. Until about 1125, medieval thinkers had access to only a few texts of ancient Greek philosophy (most importantly a portion of Aristotle’s logic). This limitation accounts for the special attention medieval philosophers give to logic and philosophy of language. They gained some acquaintance with other Greek philosophical forms (particularly those of later Platonism) indirectly through the writings of Latin authors such as Augustine and Boethius. These Christian thinkers left an enduring legacy of Platonistic metaphysical and theological speculation. Beginning about 1125, the influx into Western Europe of the first Latin translations of the remaining works of Aristotle transformed medieval thought dramatically. The philosophical discussions and disputes of the thirteenth and fourteenth centuries record later medieval thinkers’ sustained efforts to understand the new Aristotelian material and assimilate it into a unified philosophical system.

The most significant extra-philosophical influence on medieval philosophy throughout its thousand-year history is Christianity. Christian institutions sustain medieval intellectual life, and Christianity’s texts and ideas provide rich subject matter for philosophical reflection. Although most of the greatest thinkers of the period were highly trained theologians, their work addresses perennial philosophical issues and takes a genuinely philosophical approach to understanding the world. Even their discussion of specifically theological issues is typically philosophical, permeated with philosophical ideas, rigorous argument and sophisticated logical and conceptual analysis. The enterprise of philosophical theology is one of medieval philosophy’s greatest achievements.

The way in which medieval philosophy develops in dialogue with the texts of ancient philosophy and the early Christian tradition (including patristic philosophy) is displayed in its two distinctive pedagogical and literary forms, the textual commentary and the disputation. In explicit commentaries on texts such as the works of Aristotle, Boethius’ theological treatises and Peter Lombard’s classic theological textbook, the *Sentences*, medieval thinkers wrestled anew with the traditions that had come down to them. By contrast, the disputation - the form of discourse characteristic of the university environment of the later Middle Ages - focuses not on particular texts but on specific philosophical or theological issues. It thereby allows medieval philosophers to gather together relevant passages and arguments scattered throughout the authoritative literature and to adjudicate their competing claims in a systematic way. These dialectical forms of thought and interchange encourage the development of powerful tools of interpretation, analysis and argument ideally suited to philosophical inquiry. It is the highly technical nature of these academic (or scholastic) modes of thought, however, that provoked the hostilities of the Renaissance humanists whose attacks brought the period of medieval philosophy to an end.

1 Historical and geographical boundaries

The terms ‘medieval’ and ‘Middle Ages’ derive from the Latin expression *medium aevum* (the middle age), coined by Renaissance humanists to refer to the period separating the golden age of classical Greece and Rome from what they saw as the rebirth of classical ideals in their own day. The humanists were writing from the perspective of the intellectual culture of Western Europe, and insofar as their conception of a middle age corresponds to an identifiable historical period, it corresponds to a period in the history of the Latin West. The historical boundaries of medieval intellectual culture in Western Europe are marked fairly clearly: on the one end by the disintegration of the cultural structures of Roman civilization (Alaric sacked Rome in AD 410), and on the other end by the dramatic cultural revolution perpetrated by the humanists themselves (in the late fourteenth and fifteenth centuries). There is some justification, therefore, for taking ‘medieval philosophy’ as designating primarily the philosophy of the Latin West from about AD 400-1400.

There were, of course, significant non-Latin philosophical developments in Europe and the Mediterranean world in this same period, in the Greek-speaking Byzantine empire, for example, and in Arabic-speaking Islamic and Jewish cultures in the Near East, northern Africa and Spain. None of these philosophical traditions, however, was radically cut off from the philosophical heritage of the ancient world in the way the Latin-speaking West was by the collapse of the Roman Empire. For that reason, those traditions are best treated separately from that of western Europe. Accordingly, they are dealt with in this article only to the extent to which they influence developments in

medieval philosophy in the Latin West.

(See Byzantine philosophy; Hellenistic philosophy; Humanism, Renaissance; Islamic philosophy; Jewish philosophy; Medieval philosophy, Russian; Renaissance philosophy.)

2 Beginnings

The general character of medieval philosophy in the West is determined to a significant extent by historical events associated with the collapse of Roman civilization. The overrunning of Western Europe by invading Goths, Huns and Vandals brought in its wake not only the military and political defeat of the Roman Empire but also the disintegration of the shared institutions and culture that had sustained philosophical activity in late antiquity. Boethius, a Roman patrician by birth and a high-ranking official in the Ostrogothic king's administration, is an eloquent witness to the general decline of intellectual vitality in his own day. He announces his intention to translate into Latin and write Latin commentaries on all the works of Plato and Aristotle, and he gives as his reason the fear that, lacking this sort of remedial aid, his own Latin-speaking and increasingly ill-trained contemporaries will soon lose access altogether to the philosophical legacy of ancient Greece. Boethius' assessment of the situation appears to have been particularly astute, for in fact in the six centuries following his death (until the mid-twelfth century), philosophers in the West depended almost entirely on Boethius himself for what little access they had to the primary texts of Greek philosophy. Moreover, since he had barely begun to carry out his plan when his execution for treason put an end to his work, Boethius' fears were substantially realized. Having translated only Aristotle's treatises on logic together with Porphyry's introduction to Aristotle's *Categories* (see Aristotle; Porphyry) and having completed commentaries on only some of the texts he translated, Boethius left subsequent generations of medieval thinkers without direct knowledge of most of Aristotle's thought, including the natural philosophy, metaphysics and ethics, and with no texts of Plato (though a small portion of the *Timaeus* had been translated and commented on by Calcidius in the fourth century). Medieval philosophy was therefore significantly shaped by what was lost to it. It took root in an environment devoid of the social and educational structures of antiquity, lacking the Greek language and cut off from the rich resources of a large portion of classical thought. Not surprisingly, the gradual reclamation of ancient thought over the course of the Middle Ages had a significant impact on the development of the medieval philosophical tradition.

Medieval philosophy, however, was also shaped by what was left to it and, in particular, by two pieces of the cultural legacy of late antiquity that survived the collapse of Roman civilization. The first of these is the Latin language, which remained the exclusive language of intellectual discourse in Western Europe throughout the Middle Ages and into the Renaissance and Enlightenment. Latin provided medieval thinkers with access to some important ancient resources, including Cicero, Seneca, Macrobius, Calcidius, the Latin Church Fathers (see Patristic philosophy), Augustine and Boethius. These Latin sources gave early medieval thinkers a general, if not deep, acquaintance with classical ideas. Augustine is far and away the most significant of these Latin sources. His thought, and in particular his philosophical approach to Christianity and his Christianized Neoplatonist philosophical outlook, profoundly affect every period and virtually every area of medieval philosophy (see §5).

The second significant piece of late antiquity to survive into the Middle Ages is Christianity. Christianity had grown in importance in the late Roman Empire and, with the demise of the empire's social structures, the Church remained until the twelfth century virtually the only institution capable of supporting intellectual culture. It sustained formal education in schools associated with its monasteries, churches and cathedrals, and provided for the preservation of ancient texts, both sacred and secular, in its libraries and scriptoriums. Medieval philosophers received at least some of their formal training in ecclesiastical institutions and most were themselves officially attached to the Church in some way, as monks, friars, priests or clerks. In the later Middle Ages, the study of theology was open only to men who had acquired an arts degree, and the degree of Master of Theology constituted the highest level of academic achievement. Consequently, most of the great philosophical minds of the period would have thought of themselves primarily as theologians. Moreover, in addition to providing the institutional basis for medieval philosophy, Christianity was an important stimulus to philosophical activity. Its ideas and doctrines constituted a rich source of philosophical subject matter. Medieval philosophy, therefore, took root in an intellectual world sustained by the Church and permeated with Christianity's texts and ideas (see §5).

(See Aristotelianism, medieval; Augustine; Augustinianism; Boethius, A.M.S.; Clement of Alexandria; *Liber de causis*; Marius Victorinus; Nemesius; Origen; Patristic philosophy; Platonism, medieval; Pseudo-Dionysius;

Stoicism; Tertullian, Q.S.F.; Themistius; Translators)

3 Historical development

The full flowering of the philosophical tradition that grows from these beginnings occurs in the period from 1100 to 1400. Two developments are particularly important for understanding the rapid growth and flourishing of intellectual culture in these centuries. The first is the influx into the West of a large and previously unknown body of philosophical material newly translated into Latin from Greek and Arabic sources. The second is the emergence and growth of the great medieval universities.

Recovery of texts. Medieval philosophers before Peter Abelard had access to only a few texts of ancient Greek philosophy: those comprising 'the old logic' (Aristotle's *Categories* and *De interpretatione* and Porphyry's *Isagōgē*) and a small part of Plato's *Timaeus*. Abelard's generation witnessed with great enthusiasm the appearance in the Latin West of the remainder of Aristotle's logical works ('the new logic': the *Prior* and *Posterior Analytics*, the *Topics* and the *Sophistical Refutations*) (see Language, medieval theories of; Logic, medieval). Over the next hundred years, most of Aristotle's natural philosophy (most importantly the *Physics* and *On the Soul*) and the *Metaphysics* and *Ethics* became available for the first time. Not all of these Aristotelian texts were greeted with the same enthusiasm, nor did medieval philosophers find them all equally congenial or accessible (even in Latin translation). However, it is impossible to overstate the impact that the full Aristotelian corpus eventually had on medieval philosophy. The new texts became the subject of increasingly sophisticated and penetrating scholarly commentary; they were incorporated into the heart of the university curriculum, and over time the ideas and doctrines medieval philosophers found in them were woven into the very fabric of medieval thought. Having never before encountered a philosophical system of such breadth and sophistication, philosophers in the thirteenth and fourteenth centuries understandably thought it appropriate to speak of Aristotle simply as 'the Philosopher'.

As medieval thinkers were rediscovering Aristotle they were also acquiring for the first time in Latin translation the works of important Jewish philosophers such as Avencebrol (see Ibn Gabirol) and Maimonides, and Islamic philosophers such as Avicenna (see Ibn Sina) and Averroes (see Ibn Rushd). Some of their works were commentaries on Aristotle (Averroes became known simply as 'the Commentator') whereas some (such as Avicenna's *Metaphysics* and *De anima*) were quasi-independent treatises presenting a Neoplatonized Aristotelianism (see Aristotelianism in Islamic philosophy). Medieval philosophers of this period turned eagerly to these texts for help in understanding the new Aristotle, and they were significantly influenced by them. Averroes's interpretation of Aristotle's *On the Soul*, for example, sparked enormous controversy about the nature of intellect, and Avicenna's metaphysical views helped shape the famous later medieval debates about universals and about the nature of the distinction between essence and existence.

Rise of the universities. As abbot of the monastery at Bec in the 1080s, Anselm of Canterbury addressed his philosophical and theological writings to his monks. By contrast, the great philosophical minds of the next generations, thinkers such as Abelard, Gilbert of Poitiers and Thierry of Chartres, would spend significant parts of their careers in the schools at Paris and Chartres and address a good deal of their work to academic audiences. The growth of these schools and others like them at centres such as Oxford, Bologna and Salerno signals a steady and rapid increase in the vitality of intellectual life in Western Europe. By the middle of the thirteenth century, the universities at Paris and Oxford were the leading centres of European philosophical activity. Virtually all the great philosophers from 1250 to 1350, including Albert the Great, Thomas Aquinas, Bonaventure, John Duns Scotus and William of Ockham, studied and taught in the schools at one or both of these centres. It is partly for this reason that early modern philosophers (who were typically not associated with universities) refer to their medieval predecessors in general as 'the schoolmen'.

The migration of philosophical activity to the universities meant not only the centralization of this activity but also its transformation into an increasingly formal and technical academic enterprise. Philosophical education was gradually expanded and standardized, philosophers themselves became highly trained academic specialists and philosophical literature came to presuppose in its audience both familiarity with the standard texts and issues of the university curriculum and facility with the technical apparatus (particularly the technical logical tools) of the discipline. These features of later medieval philosophy make it genuinely scholastic, that is, a product of the academic environment of the schools.

The philosophical disciplines narrowly construed - logic, natural philosophy, metaphysics and ethics - occupied the centre of the curriculum leading to the basic university degrees, the degrees of Bachelor and Master of Arts. Most of the great philosophers of this period, however, went beyond the arts curriculum to pursue advanced work in theology. The requirements for the degree of Master of Theology included study of the Bible, the Church Fathers and (beginning perhaps in the 1220s) Peter Lombard's *Sentences* (which was complete by 1158). Designed specifically for pedagogical purposes, the *Sentences* is rich in quotation and paraphrase from authoritative theological sources, surveying respected opinion on issues central to the Christian understanding of the world. From about 1250, all candidates for the degree of Master of Theology were required to lecture and produce a commentary on Lombard's text. This requirement offered a formal occasion for scholars nearing their intellectual maturity to develop and present their own positions on a wide variety of philosophical and theological issues guided (often only quite loosely) by the structure of Lombard's presentation.

By virtue of its historical circumstances, medieval philosophical method had from its beginnings consisted largely in commentary on a well defined and fairly small body of authoritative texts and reflection on a canonical set of issues raised by them. Philosophers in the era of the universities took for granted a much larger and more varied intellectual inheritance, but their approach to philosophical issues remained conditioned by an established textual tradition, and they continued to articulate their philosophical views in explicit dialogue with it. Formal commentary on standard texts flourished both as a pedagogical tool and as a literary form. However, other philosophical forms, including the disputation - the most distinctive philosophical form of the thirteenth and fourteenth centuries - were essentially dialectical. In the university environment, the disputation became a technical tool ideally suited to the pressing task of gathering together, organizing and adjudicating the various claims of a complex tradition of texts and positions.

A disputation identifies a specific philosophical or theological issue for discussion and provides the structure for an informed and reasoned judgment about it. In its basic form, a disputation presents, in order: (1) a succinct statement of the issue to be addressed, typically in the form of a question admitting of a 'yes' or 'no' answer; (2) two sets of preliminary arguments, one supporting an affirmative and the other a negative answer to the question; (3) a resolution or determination of the question, in which the master sets out and defends his own position, typically by drawing relevant distinctions, explaining subtle or potentially confusing points, or elaborating the underlying theoretical basis for his answer; and (4) a set of replies specifically addressing the preliminary arguments in disagreement with the master's stated views. A disputation's two sets of preliminary arguments allow for the gathering together of the most important relevant passages and arguments scattered throughout the authoritative literature. With the arguments on both sides of the question in hand, the master is then ideally positioned to deal with both the conceptual issues raised by the question and the hermeneutical problems presented by the historical tradition. Academic philosophers held disputations in their classrooms and at large university convocations, and they used the form for the literary expression of their ideas. Aquinas' *Summa theologiae*, the individual articles of which are pedagogically simplified disputations, is perhaps the most familiar example of its systematic use as a literary device. The prevalence of the disputational form in later medieval philosophy accounts for its being thought of as embodying 'the scholastic method' (see Language, medieval theories of; Logic, medieval).

4 Doctrinal characteristics

At the most basic level, medieval philosophers share a common view of the world that underlies and supports the various specific developments that constitute medieval philosophy's rich detail.

Metaphysics. The common metaphysical ground of medieval philosophy holds that at the most general level reality can be divided into substances and accidents. Substances - Socrates and Browny the donkey are the stock examples - are independent existents and therefore ontologically fundamental. Corporeal substances (and perhaps also certain incorporeal substances) are constituted from matter and form (see Substance). Matter, which in itself is utterly devoid of structure, is the substrate for form (see Matter). Form provides a substance's structure or organization, thereby making a substance the kind of thing it is. Socrates' soul, for example, is the form that gives structure to Socrates' matter, constituting it as the living flesh and blood of a human body and making Socrates a particular human being. Accidents - Socrates' height, for example, or Browny's colour - are also a kind of form, but they take as their substrate not matter as such but a substance: Socrates or Browny. Accidents depend for their existence on substances and account for substances' ontologically derivative characteristics.

Medieval philosophers recognized matter and form, the fundamental constituents of corporeal substances, as fundamental explanatory principles. A thing's matter (or material cause) and its form (or formal cause) provide basic explanations of the thing's nature and behaviour. To these two principles they added two others, the agent (or efficient) cause and the end (or final cause). The agent cause is whatever initiates motion or change; the final cause is the goal or good toward which a particular activity, process, or change is directed.

Medieval philosophers disagreed about extensions and qualifications of this fundamental metaphysical view of the world. They debated, for example, whether incorporeal substances are like corporeal substances in being composed ultimately of matter and form, or whether they are subsistent immaterial forms. They also debated whether substances such as Socrates have just one substantial form (Socrates' rational soul) or many (one form constituting Socrates' body, another making him a living body with certain capacities for motion and cognition (an animal), and another making him a rational animal (a human being)). However, they never doubted the basic correctness of the metaphysical framework of substance and accidents, form and matter, nor are they in any doubt about whether the analytical tools that framework provides are applicable to philosophical problems generally.

(See Aristotelianism, medieval; Augustinianism; Eternity of the world, medieval views of; Platonism, medieval.)

Psychology and epistemology. Medieval philosophers understood the nature of human beings in terms of the metaphysics of form and matter, identifying the human rational soul, the seat of the capacities specific to human beings, with form. All medieval philosophers, therefore, held broadly dualist positions according to which the soul and body are fundamentally distinct. But only some were also substance dualists (or dualists in the Cartesian sense), holding in addition that the soul and body are themselves substances.

Medieval philosophers devote very little attention to what modern philosophers would recognize as the central questions of epistemology (see Epistemology, history of). Until very late in the period, they show little concern for sceptical worries and are not primarily interested in stating the necessary and sufficient conditions for the truth of the claim that some person knows a given proposition. For the most part they assume that we have knowledge of various sorts and focus instead on developing an account of the cognitive mechanisms by which we acquire it. They are especially interested in how we are able to acquire knowledge of universals and necessary truths - objects

or truths that are immaterial, eternal and unchanging - given that the world around us is populated with particular material objects subject to change. The answers medieval philosophers give to this question vary considerably, ranging from Platonistic accounts that appeal to our direct intellectual vision (with the aid of divine illumination) of independently existing immutable entities (such as ideas in the divine mind) to naturalistic accounts that appeal to cognitive capacities wholly contained in the human intellect itself that abstract universals from the data provided by sense perception (see Universals).

(See Aristotelianism, medieval; Augustinianism; Platonism, medieval.)

Ethics. Medieval philosophers share a generically Greek framework of ethical theory, extended and modified to accommodate Christianity. Its main features include an objectivist theory of value, a eudaimonistic account of the human good and a focus on the virtues as central to moral evaluation (see Eudaimonia; Areté; Virtues and vices). According to the metaphysics of goodness inherited by medieval philosophers from Greek thought, there is a necessary connection between goodness and being. Things are good to the extent to which they have being. Evil or badness is not a positive ontological feature of things but a privation or lack of being in some relevant respect. The ultimate human good or goal of human existence is happiness or beatitude, the perfection of which most medieval philosophers identified as supernatural union with God after this life. The ultimate human good is attained both through the cultivation of the moral virtues and through divine grace in the form of supernaturally infused states and dispositions such as faith, hope and charity, the so-called theological virtues (see Theological virtues).

Within this framework, medieval philosophers debated whether human beatitude is essentially an affective state (a kind of love for God) or a cognitive state (a kind of knowledge or vision of God), and whether the virtues are strictly necessary for the attainment of beatitude. They also debated whether the rightness or wrongness of some actions depends solely on God’s will. Contrary to caricatures of medieval ethics, no one unequivocally endorsed a divine command theory according to which the moral rightness (or wrongness) of *all* acts consists solely in their being approved (or disapproved) by God (see Voluntarism).

(See Aristotelianism, medieval; Augustinianism; Platonism, medieval.)

Logic and language. Medieval philosophers devote enormous attention - perhaps more attention than philosophers of any period in the history of philosophy apart from the twentieth century - to logic and philosophy of language. This phenomenon is explained primarily by the uniquely important role played by Aristotle’s logic in the development of medieval thought. Until the early twelfth century, medieval philosophers’ knowledge of Greek philosophy was restricted to a few texts of Aristotelian logic and, by default, those texts largely set the agenda for philosophical discussion. It is a passage from Porphyry’s *Isagōgē*, for example, that enticed first Boethius and, following him, a long line of commentators to take up the philosophical problem of universals (see Universals). The texts of the old logic, which remained a central part of the philosophy curriculum in the later Middle Ages, were eventually supplemented by the remaining treatises of Aristotle’s logic, among which the *Topics* and the *Sophistical Refutations* in particular sparked intense interest in the forms of philosophical argument and the nature of meaning.

(See Aristotelianism, medieval; Language, medieval theories of; Logic, medieval.)

Natural philosophy. Medieval philosophers believed that a complete account of reality must include an account of the fundamental constituents and principles of the natural realm. Their earliest reflections on these matters were inspired primarily by two ancient accounts of the origins and nature of the universe, the biblical story of creation (in Genesis) and Plato’s story of the Demiurge’s fashioning of the world (in the *Timaeus*) (see Plato). The confluence of these ancient sources produced a medieval tradition of speculative cosmological thought paradigmatically expressed in discussions of the six days of creation. This topic in particular gave medieval philosophers opportunity to reflect on the nature of the contents of the universe and the principles governing the created realm.

From the late twelfth century, medieval philosophy is profoundly affected by the new Aristotelian natural philosophy and the new scientific treatises by Islamic philosophers. Aristotle’s *Physics* in particular received enormous attention, and medieval philosophers developed sophisticated tools of logical, conceptual and mathematical analysis to deal with problems raised by Aristotle’s discussions of motion, change, continuity and infinity. Scientific treatises by Islamic thinkers such as Alkindi (see al-Kindi), Alpetragius, Avicenna (see Ibn

Sina) and Alhasen provided the material and impetus for significant developments in astronomy, medicine, mathematics and optics.

(See Aristotelianism, medieval; Eternity of the world, medieval views of; Language, medieval theories of; Natural philosophy, medieval; Oxford Calculators; Platonism, medieval.)

5 Philosophical theology

Christianity is not in itself a philosophical doctrine, but it profoundly influences the medieval philosophical world-view both from within philosophy and from outside it. On the one hand, Christian texts and doctrine provided rich subject matter for philosophical reflection, and the nature and central claims of Christianity forced medieval intellectuals to work out a comprehensive account of reality and to deal explicitly with deep issues about the aims and methods of the philosophical enterprise. In these ways, Christianity was taken up into philosophy, adding to its content and altering its structure and methods. On the other hand, Christianity imposed external constraints on medieval philosophy. At various times these constraints took institutional form in the official proscription of texts, the condemnation of philosophical positions and the censure of individuals.

Augustine laid the foundation for medieval Christian philosophical theology in two respects. First, he provided a theoretical rationale both for Christian intellectuals engaging in philosophical activity generally and for their taking Christian doctrine in particular as a subject of philosophical investigation. According to Augustine, Christian belief is not opposed to philosophy's pursuit of truth but is an invaluable supplement and aid to philosophy. With revealed truth in hand, Christian philosophers are able to salvage what is true and useful in pagan philosophy while repudiating what is false. Moreover, Augustine argued that Christianity can be strengthened and enriched by philosophy. Christian philosophers should begin by believing (on the authority of the Bible and the church) what Christianity professes and seek (by the use of reason) to acquire understanding of what they initially believed on authority. In seeking understanding, philosophers rely on that aspect of themselves - namely, reason - in virtue of which they most resemble God; and in gaining understanding, they strengthen the basis for Christian belief. The Augustinian method of belief seeking understanding is taken for granted by the vast majority of philosophers in the Middle Ages.

Second, Augustine's writings provide a wealth of rich and compelling examples of philosophical reflection on topics ranging from the nature of evil and sin to the nature of the Trinity. Boethius stands with Augustine in this respect as an important model for later thinkers. He composed several short theological treatises that consciously attempt to bring the tools of Aristotelian logic to bear on issues associated with doctrines of the Christian creed. Inspired by the philosophical analysis and argumentation prominent in these writings, medieval philosophers enthusiastically took up, developed and extended the enterprise of philosophical theology.

With the emergence of academic structure in the new European schools and universities of the twelfth and thirteenth centuries, theology became the paramount academic discipline in a formal curriculum of higher education. However, the fact that great thinkers of the later Middle Ages typically studied philosophy as preparatory for the higher calling of theology should not be taken to imply that in becoming theologians they left philosophy behind. As a simple matter of fact, later medieval theologians continued throughout their careers to address fundamental philosophical issues in fundamentally philosophical ways. And it is clear why this should be so: those who took up the study of theology were among the most gifted and highly trained philosophical minds of their day, and they brought to theology acute philosophical sensitivities, interests and skills. Moreover, insofar as they viewed Christianity as offering the basic framework for a comprehensive account of the world, they were naturally attracted to the broadly philosophical task of building on that framework, understanding its ramifications and resolving its difficulties.

Despite the dominance of the Augustinian view of the relation between Christianity and philosophy, religiously motivated resistance to philosophy in general and to the use of philosophical methods for understanding Christianity in particular emerges in different forms throughout the Middle Ages. In the twelfth century, some influential clerics saw the flourishing study of logic at Paris as a dangerous influence on theology and used ecclesiastical means to attack Peter Abelard and Gilbert of Poitiers. In the thirteenth century the new Aristotelian natural philosophy prompted another period of sustained ecclesiastical reaction. In 1210 and 1215 ecclesiastical authorities proscribed the teaching of Aristotle's natural philosophy at Paris, and in 1277 the Bishop of Paris

issued a condemnation of 219 articles covering a wide range of theological and philosophical topics. The condemnation seems largely to have been a reaction to the work of radical Averroistic interpreters of Aristotle. It is unclear how effective these actions were in suppressing the movements and doctrines they targeted.

(See Aristotelianism, medieval; Augustinianism; Averroism; Illumination; Natural theology.)

6 Scholarship in medieval philosophy

Contemporary study of medieval philosophy faces special obstacles. First, a large body of medieval philosophical and theological literature has survived in European libraries, but because many of these collections have not yet been fully catalogued, scholars do not yet have a complete picture of what primary source materials exist. Second, the primary sources themselves - in the form of handwritten texts and early printed editions - can typically be deciphered and read only by those with specialized paleographical skills. Only a very small portion of the known extant material has ever been published in modern editions of a sort that any reader of Latin could easily use. Third, an even smaller portion of the extant material has been translated into English (or any other modern language) or subjected to the sort of scholarly commentary and analysis that might open it up to a wider philosophical audience. For these reasons, scholarship in medieval philosophy is still in its early stages and remains a considerable distance from attaining the sort of authoritative and comprehensive view of its field now possessed by philosophical scholars of other historical periods with respect to their fields. For the foreseeable future, its progress will depend not only on the sort of philosophical and historical analysis constitutive of all scholarship in the history of philosophy but also on the sort of textual archeology necessary for recovering medieval philosophy’s primary texts.

Medieval philosophy, Russian

The term 'philosophy' is itself highly problematic in the context of medieval Russia. Even in its most literal sense of love of learning, it was regarded with ambivalence, its devotees risking persecution. At the same time, Russia at any given point in the Middle Ages possessed what can best be described as a self-consciousness, a sense of its own destiny. Arising from the unusual circumstances of its Conversion in 988, this consciousness continues to draw heavily on Byzantium, with Russia at first in a dependent role but later, following Constantinople's fall, assuming that of the proud successor. The centrality of the Christian element to medieval Russian thought is underlined by the continuing significance both of the monastic movement and of its ancient cradle, Kiev, even as Moscow was being extolled as the Third Rome.

1 The pre-Mongol period

Access to literate culture having been gained relatively late and as part of the Conversion to Byzantine Christianity (988), those at the forefront of intellectual life in pre-Mongol Rus' were concerned primarily with formulaic imitation of Byzantium's Christian culture. This imitative trend, coupled with the emphasis on humility and rejection of worldly glory within Byzantine Christianity itself, resulted in 'philosophy' being used as a virtual synonym for, variously, the foreign, the dangerous and the heretical. While the Greek 'philosopher' who instructs Prince Vladimir, pre-Conversion, on Christian beliefs is presented by the Chronicle as essentially a positive figure, the charges of 'philosophy' levelled at metropolitan Klim Smoliatich in the mid-twelfth century carry clear condemnatory overtones. Similarly, though book learning directed to appropriate ends was regarded as a saintly virtue, parallel cases to that of Klim demonstrate that if taken to excess it was regarded with suspicion. The popularity enjoyed by the figure of the *iurodivyi*, or fool for Christ's sake, who deliberately practised folly in order to free himself from the world and its temptations, is testament to the honouring of humility above learning.

The ideology of rejection of worldly glory proved no barrier to princely propaganda programmes, which were able to base themselves on the new religion both concretely through sumptuous new churches - again copies of the Byzantine - and abstractly by presenting the prince as defender of the Truth, battling with God's enemies.

The spiritual life of the nation, meanwhile, was influenced perhaps above all by the monasteries, headed by the famous Caves Monastery in Kiev: these foundations held a near-monopoly on literacy, learning and contemplation. It was the monasteries with their scribes which acted as a filter for the Byzantine literary heritage, neatly discarding the secular almost in its entirety; and from the monasteries came forth writers, preachers and spiritual leaders. Resonant in their words from the start is a sense of the Rus', as God's chosen, prodigal people, having been called to Christianity at the eleventh hour: prominent examples are Ilarion's *Sermon on Law and Grace* (*c*.1049) and Nestor's *Life of Feodosii of the Caves* (*c*.1088). Feodosii in particular, being one of the earliest Russian saints, and peculiarly accessible in his humility, occupied a place of honour in the developing spiritual tradition.

2 After the Mongol invasions

The sense of Russia's special destiny remains constant through the medieval period. Under the Mongols, the Church as never before became the focus of national identity, and the monastic movement in particular gained unprecedented momentum, developing a number of peculiar tendencies which were to play an important part in the nation's consciousness. Of note were the trend towards withdrawal from the world for contemplative prayer, exemplified by Sergii of Radonezh (14th century), a close advisor to the prince; and the two linked ideologies of Hesychasm and Non-Possession, which developed from it a century later under Nil Sorskii. Opposed to the Non-Possessors was Iosif Volotskii, who defended the extensive estates which the Mongols' tolerant policies had permitted the monasteries. His theory of theocratic absolutism and of the divine origin of power helped him win the self-styled Tsar of all Rus', Ivan III, defeater of the Mongols, to his side.

The growing national consciousness was bolstered by the granting of autocephalous status to the Church (1448) and by the fall of Constantinople five years later. Where Russia had been effectively in the position of a cultural dependency, on the receiving end of a one-way flow of culture and religion, it now found itself the last repository of 'Orthodoxy'. Ivan demonstratively wed Sophia Paleologos, niece of the last Byzantine Emperor, thereby

returning her to Orthodoxy from the Catholicism which, in a final indignity, the Emperor had accepted just before Constantinople fell. The ideology of ‘Moscow the Third Rome’ made its entrance: perceiving itself the sacred home of the Orthodox faith, the city assumed the trappings of the Byzantine court and Ivan took on the role of protector of the faith which had belonged to Byzantium’s emperors. In a parallel move, the Bishop of Moscow was gradually raised to the status of patriarch.

Despite the glorification of Moscow, though, Kiev, both geographically and culturally closer to the West, remained an important centre of thought. In 1631 the Caves Monastery once more demonstrated its significance when Pëtr Mogila, its hegumen, founded what was to become the Academy of Kiev, offering for the first time in Russia schooling in the classics and Western scholastic theology and philosophy. The Academy in addition embarked on translations of philosophical and theological texts, thus making them available for the first time to the Russian readership. The foundation’s significance was to continue far beyond the Middle Ages. Once the Ukraine came under full control of Moscow under Aleksei Mikhailovich, this trend spread into Russia, leading to the reform of the church books which brought about the schism in Russian Orthodoxy, as well as to the founding of a parallel Academy in Moscow and later in the other important Russian cities. Likewise, it was the Kiev Academy which was to exert a major influence over the ideas of the eighteenth-century Hryhorii Skovoroda, who can perhaps be called the first Russian philosopher proper.

Megarian school

The Megarians were a Greek 'Socratic' school of the fourth and early third centuries BC*. After their founder Euclides, whose main doctrine was the unity of the good, the leading Megarian was Stilpo, best known for preaching the self-sufficiency of virtue. They propounded various puzzles and found objections to the possible-actual distinction, the copula and universals.*

Euclides, an intimate associate of Socrates and author of Socratic dialogues, founded the Megarian (more correctly 'Megaric') school in his native Megara, a little west of Athens. His pupils included Eubulides of Miletus, who like his own pupil Alexinus of Elis was a noted propounder of paradoxes. It is not certain that these (or indeed *any* non-natives of Megara) were ever members of the Megarian school. And some other philosophical descendants of Euclides widely assumed to be Megarians, including the celebrated logician Diodorus Cronus from Iasos, in fact classified themselves as 'Dialecticians' (see Dialectical school). After Euclides, the most eminent Megarian was Stilpo of Megara, school head in the late fourth and early third centuries BC and a teacher of the founding Stoic Zeno of Citium. Only scattered evidence of their work survives.

Doctrinally, the chief focus of the Megarians was ethical and metaphysical. Despite their interest in paradoxes, there is no evidence that they shared the Dialecticians' concern with logical theory. They were primarily Socratics, but with some debt to the Eleatic Parmenides too. Euclides held that 'the good is one thing, called by many names: sometimes wisdom, sometimes god, and at other times intellect etc.', and denied the existence of its supposed opposites (Diogenes Laertius II 106). This builds on Socrates' ethical doctrine of the unity of the virtues (see Socrates §5; Stoicism §16), to which the Megarians subscribed, but may also be influenced by Parmenides' metaphysical thesis that all names, even those supposedly opposite to each other, in reality refer to a single being (see Parmenides §7). The upshot seems to be a monism of value (possibly even entailing that the world is entirely good), but not the Eleatic metaphysics that some have attributed to the school.

That they were not considered Eleatic by their contemporaries is clear from Aristotle's treatment of their modal doctrine: only what is actual is possible, for example, only when he is building is a builder capable of building. Aristotle objects (*Metaphysics* IX 3) that this would eliminate all change - an Eleatic-sounding outcome which he implies they would not welcome.

Stilpo resembled the Cynics in his insistence on the autonomy of human good. Asked whether he had lost anything in the sack of Megara, he gave the famous reply that he had lost nothing that was his - meaning that moral and intellectual attainments are inalienable. He raised objections to the copula, dismissing all '*x* is *y*' statements as false identity-statements. An argument of his against Platonic Forms suggests a similar worry: you cannot say 'This is a vegetable', because vegetable (the universal) existed thousands of years ago, whereas this did not.

'Megarian questionings' acquired the reputation of sophistic arguments. Nevertheless, they may have included the important logical puzzles propounded by Eubulides, such as the sorites ('When does a collection of grains become a heap?'), the horned argument ('Have you lost your horns?'), the veiled argument ('You don't know the hooded man? He is your father. So you don't know your father.') and the liar paradox ('Is "I am lying" true or false?').

Meinecke, Friedrich (1862-1954)

Friedrich Meinecke was a German historian of moral and political ideas who addressed the problems of his age through critical study of the writings of past thinkers. He studied at the universities of Berlin and Bonn, before becoming a state archivist in Berlin for fourteen years. He went on to hold professorships at Strasbourg, Bonn and Berlin. He contributed to political thought through books on cosmopolitanism and nationalism, on the morality of states and on historicism. In these works he re-examined the European tradition of moral and political thought, attempting especially to find a middle way between the universalist and cosmopolitan ethic of the Enlightenment and the nineteenth-century belief in the particularity and historical uniqueness of national cultures. His life spanned the entire period from Bismarck to Hitler, and he sought to bring his deep historical learning to bear on the ethical dilemmas facing Germans during this time.

Friedrich Meinecke was the last great representative of the German Historical School, which began with Niebuhr and Savigny and enjoyed a prolonged flowering in such figures as Ranke, Mommsen, Treitschke, Sybel, Droysen and, in Meinecke’s own day, Otto Hinze, Ernst Troeltsch, Erich Marcks and Hans Delbrueck (and, although more loosely associated with it, Max Weber). His more remote, but none the less omnipresent, intellectual ancestors were Goethe, Herder, and Wilhelm von Humboldt. His awareness of a deep affinity with the great Swiss cultural historian, Jacob Burckhardt, whose profundity of vision and melancholy pessimism contrasted with the more uncomplicated, optimistic outlook of Ranke and the Prussians, only grew with time. He virtually created the history of ideas in Germany as a separate, highly sophisticated and self-conscious discipline bestraddling both history and philosophy; and, although an individualist who respected individuals, displaying no apparent desire to be seen as the founder of a school (his desire for power in this as other matters was practically nonexistent), he nevertheless became the undisputed doyen of several generations of German historical scholars. His many US pupils, as well as the scholar refugees who fled the Third Reich, sowed the seeds of his historical approach in the USA. Never in the political limelight himself, Meinecke did informally advise politicians and public figures, particularly during the Weimar Republic, but his greatest contribution to political thought and practice is to be found in his three major works.

Weltbürgertum und Nationalstaat (Cosmopolitanism and the National State) (1907) was written in that period of liberal bourgeois optimism before the First World War which tended to see a harmony between intellect and power embodied in the state. To uncover the roots of the modern age was a central aim of German historians at this time: as Max Weber had discovered the source of the capitalist world in Calvinism, and Ernst Troeltsch had traced the links between modern culture and Protestantism, so Meinecke went in search of the origins of modern national consciousness. In a series of loosely connected individual studies, he submitted the views of the men and movements that influenced and finally brought about German unification to minute and sensitive analysis. From the cosmopolitan Enlightenment figure of Wilhelm von Humboldt, through early Romantics such as Novalis and Friedrich Schlegel, to the theorists of the state, Fichte and Adam Müller, and the practical reformers, vom Stein and Gneisenau, down to the later Hegel, Ranke and Bismarck, Meinecke sketched forth the gradual transition from German eighteenth-century cosmopolitanism to nineteenth-century nationalist particularism. Elements of the older, universal, humanistic outlook lingered on in the new ideology, but a novel world not wholly favourable to them had been born. Yet, at this stage Meinecke still hoped, rather idealistically, that the old values and the new could co-exist in harmony. Although, in the words of one sympathetic German critic, this book moves ‘in the rarefied air of the highest intellectual regions’, it is considered by many to be Meinecke’s greatest work, and it had a permanent impact on subsequent German historiography.

Meinecke’s second great work was *Die Idee der Staatsräson in der neueren Geschichte (The Doctrine of Raison d’état in the Modern Age)* (1925). Written in the aftermath of the First World War and the collapse of the Hohenzollern monarchy, this is a magisterial survey of the conflict between ethics and politics as exemplified by thinkers and men of action ranging from Machiavelli, Richelieu, and Montesquieu, to Frederick the Great, Hegel, Bismarck and Treitschke. Bringing immense insight and subtlety to the analysis of ideologies, Meinecke presents the history of political thought and action - in Germany at least - as a long chain of triumphs of the naked will to power in the service of the state over common morality, whether Christian or Kantian, and arrives at the bitter insight that, ‘[t]he state, so it seems, must violate the moral law’ (1925 (1957)). The optimistic idealism of

Weltbürgertum und Nationalstaat yields to a sombre, unsentimental recognition of the amorality and cynicism of governments. Nevertheless, Meinecke still insists that wielders of public power should act as guardians and promoters of a common ethical code, and that '[t]he state must become moral and strive for harmony with the universal moral law' (1925 (1957)). A view of history emerges which seeks to avoid the twin extremes, on the one hand, of the positivistic Enlightenment optimism of progress, Hegelian panlogism and Rankean faith in Providence, and, on the other hand, the yawning chasm of Schopenhauerian historical pessimism. The result is a clash between historical experience and the ethical imperative. Yet this tragic view does not exclude the possibility of genuine personal and historical greatness; rather, it requires it and makes it possible. For Meinecke the fact that historical man is constantly called upon to be a hero or an actor in a tragedy is what gives history its universal import and significance.

With the advent of national socialism, Meinecke was dismissed as 'an historical epigone' and divested of his chair and his editorship of *Historische Zeitschrift*. His last major work, *Die Entstehung des Historismus (The Rise of Historicism)* (1936), represents a vast stock-taking. Here Meinecke reaches out beyond the German cultural sphere to embrace Italian, French, and English figures in a grand survey of the emergence of modern historical consciousness itself. Examining such figures as Shaftesbury, Vico, Montesquieu, Herder and Goethe, he traces the profound shift from the static, rationalist, universalist presuppositions of the Renaissance, the Age of Reason, and the Enlightenment, themselves rooted in the much older tradition of Natural Law, to the new historicist, relativist insights into the nature of man and human history that mark our own era. The generalizing, typifying methodology which the older classical tradition shares with the sciences gives way increasingly to the genetic approach with its emphasis on origins, development, organic growth, and on the role of unique creative individuals and groups - nations, cultures, churches, peoples, races, and so on. He thus unearthed the roots of much that came later, including Ranke and the Historical School itself, Romanticism, and twentieth-century currents of relativism and irrationalism.

Die Entstehung des Historismus aimed above all to secure the autonomy of the historical realm and to protect it especially against 'scientistic' incursions, not least by figures such as Spengler with his crude and simplistic biological categories. History begins with creative human freedom 'where the spontaneous factor of human beings acting in the light of values intervenes decisively and thus creates something unique and singular' (1936 (1972)). Not only states and historical epochs are individualities on Meinecke's view, but also ideas and ideals. These are to be studied not only for their causal efficacy, but most of all for their intrinsic value and power to illuminate. They must be infused 'with as much life-blood' as the historian has to give them: 'The essence of history is not the political battle for power but the creation of lasting cultural values' (1936 (1972)).

In *Die Deutsche Katastrophe (The German Catastrophe)* (1946), Meinecke offers a brilliant and profound analysis of Germany's moral and political collapse. Among the ruins of the Bismarck-Hitler era, a path must be found back to the Age of Goethe. Meinecke's last book, *Schaffender Spiegel - Studien zur Deutschen Geschichtsschreibung und Geschichtsauffassung (The Creative Mirror: Studies in German Historiography)* (1948), contains studies on various aspects of 200 years of German historiography and is notable for his agonized reflections on the intractable problems of relativism thrown up by the historicist outlook he did so much to encourage.

Meinecke has often been accused of lacking sharp conceptual clarity and of ignoring material and economic factors in history. Particularly critical are Marxist historians. Yet none of this detracts from his unique achievement in unearthing the genesis and nature of the hitherto unexamined intellectual structures that underlie political thought and action in the modern world, and in describing them with a depth and breadth of minutely detailed learning, and a refined sense of nuance and atmosphere, probably unparalleled in his time or since.

Meinong, Alexius (1853-1920)

Meinong was an Austrian philosopher and psychologist who taught at the University of Graz. He contributed substantially to psychology, epistemology, value theory, ethics and probability theory, but is best known for his theory of objects, in which he advocates the radical view that there are objects which are wholly outside being, including impossible objects. Meinong influencedRussell and the American 'new realists'. Though widely rejected, his views have proved difficult to refute decisively and he has found sympathetic support from a number of logicians and philosophers.

1 Life, works and development

Alexius Meinong studied history at the University of Vienna, where he came under the influence of Franz Brentano, and turned to philosophy and psychology. His earliest works, the *Hume Studien* (Hume Studies) of 1877 and 1882, the first being his *Habilitationsschrift*, examined the nominalism of Locke and Hume and their theories of relations.Meinong thus grew up in the British philosophical tradition, rather than the German. After a short period as *Privatdozent* in Vienna, he moved in 1882 to Graz, where he remained until his death. In 1894 he established Austria's first psychology laboratory. A devoted teacher, he acquired talented students, including Ernst Mally, the psychologist Vittorio Benussi, andStephan Witasek, whose early deathMeinong described as the greatest blow of his life. Meinong's eyesight deteriorated early in life and he preferred to remain in Graz rather than accept a professorship in Vienna. Married and with a son, he was a competent violinist and composed *Lieder*.

Meinong's views developed slowly. Until the turn of the century his main work was in epistemology, psychology and the theory of value. Under the influence of Ehrenfels and Twardowski he turned to ontological concerns. *Über Annahmen (On Assumptions)* (1902, 2nd edn 1910) first introduced objectives, special objects of judgment, while the idea of a science of objects outside being occurs in the programmatic essay 'Über Gegenstandstheorie' ('On the Theory of Objects') (1904). These works attracted the notice of Bertrand Russell, and a controversy developed over the question whether it was logically consistent to assume impossible objects. Meinong responded to Russell's criticisms with refinements, but did not relinquish his position. His ontological views reached their final form with the publication of *Über Möglichkeit und Wahrscheinlichkeit (On Possibility and Probability)* (1915) and *Über emotionale Präsentation (On Emotional Presentation)* (1917). Two volumes of collected essays were published during his lifetime, and an eight-volume *Gesamtausgabe (Complete Edition)* appeared from 1968 to 78.

Meinong's style is clear but ponderous, and few of his many terminological coinages have passed into German philosophical currency. His views have been largely neglected in the German-speaking world, finding more resonance, both positive and critical, in English-language philosophy.

2 Intentionality and objects

FollowingBrentano, Meinong viewed the intentionality of the mental as its defining characteristic, but whereas Brentano originally regarded objects of consciousness as immanent, by 1890 Meinong was distinguishing an immanent from an external sense of 'object' (see Intentionality). FollowingTwardowski, Meinong then reserved the term 'object' (*Gegenstand*) for the external referent, denoting the immanent aspect by 'content' (*Inhalt*). He adoptedTwardowski's view that all mental acts have objects, but that some such objects are nonexistent. This was the basis for the development of the theory of objects outside being. Meinong called the relation between object and subject 'presentation' (*Präsentation*).

Meinong's classification of mental acts also deviated from that of Brentano. He distinguished ideas (*Vorstellungen*), thoughts, feelings and desires. Whereas for Brentano all thoughts are judgments, Meinong added conjectures (*Vermutungen*) and assumptions (*Annahmen*), which may be playful or hypothetical: like judgments, they are positive or negative and may be true or false, but, like ideas, they do not involve intellectual commitment. This distinction between 'serious' and 'phantastic' acts was extended into the emotive and conative spheres. Each kind of act, whether serious or phantastic, came to have its own characteristic kind of object: ideas correspond to things (*Objekte*), for example, Graz, greenness; thoughts correspond to objectives (*Objektive*), for example, that Graz is in Styria; feelings or emotions correspond to dignitatives, such as the beauty of Graz; and desires correspond to desideratives, for instance, that Graz should have less traffic. Things and dignitatives are

designatable by names whereas objectives and desideratives are designatable by clauses.

Meinong's rich ontology is thus the joint product of a unified conception of intentionality as presenting independent objects, and a rich taxonomy of the mental.

3 Objects outside being

Practical life enjoins attention to things around us, but in thought we range beyond what Meinong called the 'actual' or existent. Originally inclined to nominalism, Meinong progressively enlarged his ontology and came to decry the 'prejudice in favour of the actual'. Objectives, which resemble both 'states of affairs' and Russell's 'propositions', divide into those that are 'factual' or obtain, for example, that Graz is in Austria, and those that are 'unfactual' or do not obtain, for example, that Graz is in Slovenia. Meinong called 'true' only those factual objectives which someone grasps as factual. He regarded obtaining (*bestehen*) as a kind of timeless being: unfactual objectives are outside being (*außerseiend*). Similarly there exists no golden mountain, but the golden mountain is just as golden and mountainous as any existent: *what* and *how* a thing is is independent of *whether* it is. The converse does not hold: impossible objects, such as the round square, cannot exist.

Possible but non-actual objects had been accepted before, but Meinong's impossible objects were a largely new departure. Meinong recognized this and proposed a new, existentially uncommitted (*daseinfrei*) science, the theory of objects. It was impossible objects to which Russell took exception: his theory of descriptions aimed to dispense with all non-beings (see Russell, B. §9). Russell claimed thatMeinong's impossible objects offended against the law of contradiction. Meinong agreed but was unperturbed: his understanding of 'law of contradiction' derived from traditional logic, which said that a thing cannot both have and lack a certain property, whereas Russell meant that a proposition and its contradictory could both be inferred. Russell tried again: the *existent* round square is existent, round and square, and so it both exists and does not. Meinong replied that being existent is part of the existent round square's nature, whereas existing is not: being existent does not entail existing. Russell saw no difference and dropped the matter, satisfied he was right, but Meinong's view is in the tradition ofKant. Existence is not a (normal) property, though it has a 'watered-down' counterpart, being-existent. Meinong divided properties generally into two kinds, 'nuclear' ones which are part of the nature of a thing, and 'extra-nuclear' ones, such as existing, being simple or being complete, which are not.

Paradoxical objects such as Russell's set of all non-self-membered sets were harder to accommodate.Meinong called them 'defective objects', but could not decide whether they were just very deviant objects or whether there were none at all.

4 Incomplete objects and modality

'Incomplete' objects lack being for a different reason: they are undetermined one way or the other with respect to at least one property. The golden mountain, for instance, is undetermined with respect to its height. Meinong pressed incomplete objects into service as the senses of predicates and as epistemological intermediaries: in seeing a table I do not see all its characteristics, so the incomplete object corresponding to my perception is an 'auxiliary' object giving me access to the 'target' object, the table itself. An incomplete object with its suite of properties has a parasitic or 'implexive' being in the complete objects which have those properties.

In Meinong's theory of objective possibility and probability, incomplete objects are where possibility is 'at home'. Suppose I am about to throw a (fair) die. The actual throw will be a three, or not a three, but my thought that there is a one in six chance that I will throw a three has an objective foundation in that incomplete object, 'my next throw of the die'. This is subject of the objective 'that my next throw of the die will be a three', which is neither factual, nor unfactual, but 'subfactual'. It has a degree of factuality of 1/6, properly between 1 (factual) and 0 (unfactual). Meinong thus reconciled classical determinism with an objective foundation for probability statements, and showed the possibility of many-valued logic, which was later developed by Jan Łukasiewicz, who attended some of his lectures (see Łukasiewicz, J. §3).

Meinong considers necessity and impossibility to attach to objectives, not because of factuality or unfactuality in all possible worlds, but because their factuality and unfactuality are, he says, 'inhesive' to them. Notably, Meinong never considers God or any other supposedly necessary being.

5 Psychology and epistemology

Meinong carried out rudimentary classroom demonstrations in Vienna and Graz, and from this activity the Graz laboratory arose. His psychological studies were largely in the service of his epistemological interests, and his contributions were more empirical than those of Brentano. He examined among other things the psychology of abstraction, colour and Gestalt perception, phantasy, eye-movement, the feelings accompanying judgments, and sensory fatigue. His analysis of the role of indirect measurement in Weber's psychophysical law was noted by Russell. *On Assumptions* aimed originally at establishing the classificatory proposition that assumptions are different from both judgments and ideas; only in the course of writing did Meinong discover that he needed to consider objectives, the objects of judgment and assumption, for themselves. As object theory came to dominate Meinong's thinking, he left psychological experimentation to others and, like Husserl, rejected undue philosophical reliance on psychology, while allowing it an honourable role. The 1912 essay 'Für die Psychologie und gegen den Psychologismus in der allgemeinen Werttheorie' (For Psychology and Against Psychologism in General Value Theory) shows him striking this balance.

Meinong published several monographs and papers on epistemology, including studies on memory, conjectural conviction, the experiential basis of knowledge and an attempt to prove universal causality by inductive reasoning. The admission of conjectural conviction (*Vermutungsevidenz*), which, by contrast with Brentano's *Evidenz*, is fallible and may be inductively improved, is part of Meinong's general concern to describe those supposedly defective acts of mind often neglected by epistemologists. Our knowledge of the external world is for Meinong conjecturally, not apodictically certain. We have no reason to doubt it, but it is a posteriori and we might conceivably be mistaken. Meinong's work in epistemology has been less influential than in other areas, perhaps because he was never tempted by racy positions such as scepticism or idealism.

6 Value theory and ethics

In Vienna Meinong attended economics lectures by Carl Menger, and his own value theory attempts to extend the theory of value beyond economics, on the basis of our valuing experiences. Rejecting Brentano's assimilation of feeling to desire and will, he considered feeling or emotion to be the predominant source of value. Early lectures in Vienna, systematized in his *Psychologisch-ethische Untersuchungen zur Werth-Theorie (Psychological-ethical Investigations in Value Theory)* (1894) prompted his student Ehrenfels to counter with a subjectivistic desire-based theory, and in their constructive and friendly disagreement they conceded that value might attach *derivatively* to desires (Meinong) or feelings (Ehrenfels).

Meinong's views on value, like those on cognition, became progressively more objectivistic, and in his last works he staunchly upheld what he called 'impersonal' values, which we can recognize but do not create. Meinong's patient dissection of the principles governing values and valuation paved the way for Ernst Mally's first excursion into deontic logic.

7 Philosophy as a discipline

Meinong regarded philosophy as a congeries of disciplines rather than a single science, and his painstaking piecemeal method of philosophizing 'from below' contrasted with bolder systems and programmes. He described himself as an empirical thinker, but not an empiricist, and just this willingness to be led by the data was what recommended him to the young Russell. Nevertheless, his 'empirical thinking' led him to revolutionary conclusions, and towards the end of his life he can be seen connecting the pieces together. Meinong considered *On Emotional Presentation* to be his most important work, spanning psychology, epistemology, object theory and value theory in a single arch.

PETER SIMONS

List of works

Meinong, A. (1968-78) *Alexius Meinong Gesamtausgabe (Complete Edition)*, 7 vols, and *Ergänzungsband (Supplementary Volume)*, Graz: Akademische Druck- und Verlagsanstalt.(Contains all the books and essays that Meinong published, together with his intellectual self-portrait (*Selbstdarstellung*) and major reviews. Volume 7 contains a comprehensive index. The supplementary volume contains a selection of posthumous material including lecture notes, notes on other philosophers' writings, and a lexicon of logic and

epistemology.)
Meinong, A. (1877) ‘Hume-Studien I. Zur Geschichte und Kritik des modernen Nominalismus’, *Sitzungsberichte der philosophisch-historischen Klasse der Kaiserlichen Akademie der Wissenschaften (Wien)* 87: 187-260; published separately, Vienna: Gerold; repr. in *Gesamtausgabe*, 1: 1-72; trans. K.F. Barber, in *Meinong's Hume Studies. Translation and Commentary*, Ann Arbor: University Microfilms, 1966, 98-192.(Distinguishes extreme (linguistic) from moderate (conceptualistic) nominalism and upholds the latter.)
Meinong, A. (1882) ‘Hume-Studien II. Zur Relationstheorie’, *Sitzungsberichte der philosophisch-historischen Klasse der Kaiserlichen Akademie der Wissenschaften (Wien)* 101: 572-752; published separately, Vienna: Gerold; repr. in *Gesamtausgabe*, vol. 1; partially trans. K.F. Barber, in *Meinong's Hume Studies. Translation and Commentary*, Ann Arbor: University Microfilms, 1966, 194-229.(An early investigation of the ontology and epistemology of relations, with reference to Hume.)
Meinong, A. (1894) *Psychologisch-ethische Untersuchungen zur Wert-theorie* (Psychological-ethical Investigations in Value Theory), Graz: Leuschner & Lubensky; repr. in *Gesamtausgabe*, vol. 3, 1-244.(An ethics and value theory based on feelings as the primary bearers of value.)
Meinong, A. (1902) *Über Annahmen*, Leipzig: Barth, 2nd, revised edn, 1910; repr. in *Gesamtausgabe*, vol. 4; trans. and ed. J. Heanue, *On Assumptions*, Berkeley, CA: University of California Press, 1983.(The theory of assumptions and objectives. Probably Meinong's most influential work.)
Meinong, A. (1904) ‘Über Gegenstandstheorie’, in A. Meinong (ed), *Untersuchungen zur Gegenstandstheorie und Psychologie*, Leipzig: Barth, 1-50; trans. and ed. R.M. Chisholm, ‘The Theory of Objects’, in *Realism and the Background of Phenomenology*, Atascadero, CA: Ridgeview, 1982, 76-117.(The programme for the theory of objects. The whole 1904 collection, a showcase for the Graz School, was reviewed by Russell (1905).)
Meinong, A. (1912) ‘Für die Psychologie und gegen den Psychologismus in der allgemeinen Werttheorie’ (For Psychology and Against Psychologism in General Value Theory), *Logos* 3: 1-14; repr. in *Gesamtausgabe*, vol. 3, 267-82.(While values are not all psychological or ‘personal’, psychology is of value to value theory.)
Meinong, A. (1915) *Über Möglichkeit und Wahrscheinlichkeit. Beiträgezur Gegenstandstheorie und Erkenntnistheorie* (On Possibility and Probability), Leipzig: Barth; repr. in *Gesamtausgabe*, vol. 6.(Part 1 deals with ‘objective’ probability, understood in terms of incomplete objects and subfactual objectives. Part 2 concerns our subjective awareness of probability. Meinong's most mature object-theoretic work.)
Meinong, A. (1917) ‘Über emotionale Präsentation’, *Sitzungsberichte der Akademie der Wissenschaften in Wien, philosophisch-historische Klasse* vol. 183 (appeared in 1924); also published separately, Vienna: Holder,1917; repr. in *Gesamtausgabe*, vol. 3, 283-476; trans. and ed. M.-L. Schubert Kalsi, *On Emotional Presentation*, Evanston, IL: Northwestern University Press, 1972.(Emotions present independent value-bearers in much the same way as perception and thought present independent objects. Includes an inconclusive discussion of paradoxical (‘defective’) objects.)
Meinong, A. (1921) ‘A. Meinong [Selbstdarstellung]’, Leipzig: Meiner, vol. 1, 91-150; 2nd edn, 1923, 101-160; repr. in *Gesamtausgabe*, vol. 7, 1-62; biography and section on theory of objects trans. R. Grossmann, in *Meinong*, London: Routledge & Kegan Paul, 224-36.(Short but revealing account by Meinong of his own life, works and views, written shortly before his death.)
Meinong, A. (1965) *Philosophenbriefe. Aus der wissenschaftlichen Korrespondenz von Alexius Meinong (Philosophical Correspondence)*, ed. R. Kindinger, Graz: Akademische Druck- und Verlagsanstalt.(A selection of 43 letters to philosophers written between 1882 and 1920. Includes correspondence withRussell and Husserl.)

Meister Eckhart (*c.*1260-1327/8)

More than any other medieval thinker, Eckhart has received widely divergent interpretations. The controversies stem from the fact that his writings fall into two distinct groups, works written in the vernacular and works written in Latin. The German writings, which were intended for a wide audience, established Eckhart's long-standing fame as a mystic. Another, more academic Eckhart emerged when his Latin work was rediscovered in 1886. The study of Eckhart's thought today centres on the unity of the scholastic (Latin) and the popular (German) work.

Eckhart was born about 1260 at Hochheim, Germany, and died in 1327 (or early 1328), probably at Avignon. After entering the Dominican Order, he studied theology at the *studium generale* of the Order in Cologne. In 1302-3 he was Master of Theology at the University of Paris. In the next years he held executive functions within his Order in Germany. A token of the high esteem Eckhart enjoyed is that in 1311 he occupied the Dominican chair of theology at Paris for a second time (an honour that also fell to Thomas Aquinas). Thereafter he was the spiritual master of religious communities and a teacher in Cologne. In 1326 the archbishop of that city started an inquiry into his doctrines on suspicion of heresy. Eckhart appealed directly to the pope in Avignon, but died before the conclusion of the trial. In the bull *In agro dominico* of 27 March 27 1329, Pope John XXII condemned twenty-eight propositions taken from his works and sermons.

Eckhart's main Latin work is the *Opus tripartitum*. As the title indicates, it was intended to consist of three parts: the *Opus propositionum (Work of Propositions)* in which a thousand propositions were to be explained; the *Opus quaestionum (Work of Questions)*, consisting of questions arranged according to the order of Thomas Aquinas' *Summa theologiae*; and the *Opus expositionum (Book of Expositions)*, containing commentaries on scripture and sermons. It is unknown whether Eckhart ever completed this grand project. Only fragments of it have come down to us: the General Prologue and the prologue to the *Opus propositionum*, five questions disputed at Paris, and several commentaries on scripture (Genesis, Exodus, the Book of Wisdom and the Gospel according to John) that were certainly intended to be part of the*Opus propositionum*.

An important clue to Eckhart's self-understanding is to be found in the prologue of his commentary on the Gospel according to John. There he states that in all his works his intention is to expound the doctrines taught by the Christian faith by means of the natural arguments (*rationes naturales*) of the philosophers. This intention is clarified at the beginning of the General Prologue of the *Opus tripartitum* by some preliminary remarks, which Eckhart apparently considers basic to the interpretation of the whole work. According to one of these remarks, the second and third work of the work are so dependent on the *Opus propositionum* that without it they are of little use. He illustrates his method by stating the first proposition ('Being is God'), the first question ('Does God exist?') and the first commentary on a text ('In the beginning God created heaven and earth'), and by showing how the proposition provides the answer to the question and elucidates the text. Eckhart's procedure implicitly criticizes the method of scholastic science. Aquinas' *Summa theologiae*, for instance, consists of thousands of concrete *quaestiones*, whose solution is founded on general principles, which are, however, not explained but presupposed (see Aquinas, T.). In Eckhart's view, the scholastic method requires an axiomatic metaphysics.

A specification of this metaphysics is given in Eckhart's first remark in the General Prologue. The most general terms (*termini generales*), such as 'being', 'one', 'true' and 'good', should by no means be thought of as accidents. 'Being' and the terms convertible with it are not added to things as though posterior to them; on the contrary, they precede everything and are primary in things. The first four treatises of the *Opus propositionum* would deal with these most general terms, which are called *transcendentia* in the Middle Ages. They provide the philosophical foundation of the *Opus tripartitum*. Eckhart identifies the transcendentals with the divine; God alone is properly being, one, true and good. Every other thing is specified through its form to *this* or *that* being.

One of the problems in studying Eckhart is how the identification of God and *esse* in the *Opus tripartitum* can be reconciled with his criticism of ontotheology in the *Quaestiones Parisienses* (the questions disputed at Paris). In the latter, he argues that God is not being (*esse*), but understanding (*intelligere*). He observes ironically that the Evangelist John did not say 'In the beginning was being, and God was being', but 'In the beginning was the Word, and the Word was God'. Being belongs to the domain of the finite, the created.

Eckhart’s German writings comprise numerous sermons and several spiritual treatises: *Reden der Unterweisung (Talks of Instruction)*, *Vom edlen Menschen (The Nobleman)* and *Das Buch der göttlichen Tröstung (The Book of Divine Consolation)*. In one of his sermons (53), Eckhart remarks that he usually preaches about just a few themes. His favourite theme is *Abgeschiedenheit* (detachment), and to it he devoted a separate treatise (*Vom Abgeschiedenheit*), which describes it as the highest virtue, higher even than love. The human person must empty itself and strip off the creaturely conditions of *this* or *that* being. It is by the virtue of detachment that a human being can be most closely united with God. The second theme is the birth of the Son or the Word in the soul. The unity of God the Father and God the Son is for Eckhart the model of the union of the soul with God (see Trinity). The third theme is the ‘nobility’ that God placed in the ‘innermost’ part of the soul. Eckhart calls it the ‘spark of the soul’, which consists in the intellect. ‘If the soul were entirely of this nature, it would be wholly uncreated and uncreatable.’ This proposition was one of those condemned in the trial of Eckhart, but in his apology he denied wiping out the boundaries between God and creature. He wrote that he had never taught that there is something in the soul which is uncreated, ‘because then the soul would be composed of created and uncreated’. A human being is not pure intellect (see Soul, nature and immortality of the).

Melanchthon, Philipp (1497-1560)

Philipp Melanchthon was one of Luther's closest associates, helping to systematize Lutheran theology, and his Loci communes (Commonplaces) (1521) was one of the most influential early works of Protestant theology. He was often a moderating influence in theological debates between Catholics and Protestants. Melanchthon was also involved in controversy over the relationship between human will and God's grace in the achievement of salvation. He was responsible for the reform of Protestant German education in the sixteenth century, through the large number of textbooks which he composed, and through his revisions of the statutes of universities (notably Wittenberg) and schools. As a scholar and reformer of education, he was a staunch follower of the humanism of Agricola and Erasmus, committed to teaching the best Latin authors and the Greek language. Many of his works are textbooks (often produced in different versions), frequently based on lecture notes, summarizing or commenting on classical authors or scripture. Although more important as a summarizer and popularizer than as a source of new ideas, Melanchthon nevertheless made important contributions to the development of logic, rhetoric, ethics and psychology, as well as to aspects of Reformation theology. In logic he contributed to the growth of interest in method. In ethics he established a place for classical moral teaching alongside but subordinate to the teaching of the Bible. His favourite philosopher was Aristotle, and he tended to pour scorn on rival ancient schools of philosophy. In psychology he favoured a simplified Aristotelianism, close to medieval faculty psychology, with strong emphasis on links with biology. He opposed scepticism wherever he encountered it.

1 Reformer of German education

Philipp Melanchthon, born Philipp Schwarzerd at Bretten, received a humanist elementary education, under the influence of his great-uncle, the famous Hebrew scholar and friend of Agricola, Johann Reuchlin. Starting out with Greek and a good knowledge of Latin literature, he was bored by the complex dialectical disputes of the traditional arts course at the University of Heidelberg, where he studied from 1509. His real education came, he said, at the University of Tübingen, where he studied from 1512. In the letter-preface to his *Opera omnia (Complete Works)* (1541) he mentions the importance of Oecolampadius' gift to him, in 1516, of a copy of the first edition of Rudolph Agricola's *De inventione dialectica (On Dialectical Invention)* (1479) (see Agricola, R. §2). In 1518 he was called to the newly founded chair of Greek at Wittenberg, where he came strongly under Luther's influence, enrolling in the theology faculty in 1519. In 1521 he produced the *Loci communes (Commonplaces)*, which attempts a systematic presentation of Protestant theology. Luther described it as 'a book which ought to be esteemed next to the Bible'. Melanchthon surprised his fellow humanists with the strength of his initial endorsement of Luther's views on the corruption of humanity, the enslavement of the will, and justification by faith alone (see Luther, M. §3). In the 1530 version of the *Loci communes* he modified these views somewhat, and in the 1543 version went even further, approaching Erasmus' position on the freedom of the will, and the need for the will to cooperate with the Holy Spirit in order to obtain grace (see Erasmus, D.).

He took part in several of the most famous debates of the early Reformation, including the Colloquy of Marburg (1529) and the Diet of Augsburg (1530). He was the main author of the Augsburg Confession, an authoritative statement of Lutheran doctrine, expressed in the most conciliatory language possible. Strict Lutherans sometimes regarded him as too willing to concede ground to Rome, particularly in the Leipzig Interim (December 1548), an attempt to make peace between Protestants and Catholics. In later life he gave most attention to writing textbooks, to the organization of church and schools, and to controversies with the Calvinists.

Melanchthon's most important contribution to Lutheran theology was his concept of forensic justification, which represents a development of Luther's ideas. According to Melanchthon, the sinful human being is declared to be righteous in God's heavenly court. This is an imputation by God rather than a change in the nature of the individual. This doctrine, which seems to be connected with Melanchthon's humanist interest in Roman legal practice, marks a strong distinction between the Protestant approach to justification and that of Augustine. However (as often in Melanchthon) this firm position is weakened by some of his other comments on the fourth article of the Augsburg Confession which state that a real change does take place.

Melanchthon soon came to dominate Wittenberg University. He was responsible for several reforms of the

Wittenberg statutes, and for giving reformed or new statutes to other Protestant German universities (including Tübingen and Leipzig) and schools (for example in Eisleben, Magdeburg and Nuremberg). As an educational reformer his first commitment was to humanism and to the teaching of ancient languages, but he also placed a strong emphasis on mathematics and physics. Thus in his programme for the Wittenberg arts faculty in 1536, of ten lecturers there were one each for Hebrew, Greek, poetics, Latin grammar and literature, physics and moral philosophy, and two each for rhetoric with dialectic and mathematics. In 1546, the lecturers on poetics and moral philosophy, and one of the rhetoric/dialectic teachers made way for lecturers on physics with botany and two more teachers of Latin literature.

2 Dialectic and rhetoric

Between 1518 and 1547 Melanchthon wrote six books on rhetoric and dialectic. His *De rhetorica libri tres (Three Books on Rhetoric)* (1519) was mainly concerned with invention (the part of rhetoric concerned with generating the material of a composition). He insisted on the close connection between rhetoric and dialectic, as had Rudolph Agricola. He next took the connection further by producing coordinated manuals of both subjects: *Compendiaria dialectices ratio (Compendious Method of Dialectic)* (1520) and *Institutiones rhetoricae (Training in Rhetoric)* (1521). In these books Melanchthon divided the two subjects in a more traditional way than Agricola had done or Ramus was to do. Later in his career he wrote two further coordinated manuals, *Dialecticae libri quatuor (Four Books of Dialectic)* (1528) and *Elementa rhetorices (Elements of Rhetoric)* (1531). These were intended as introductions to Agricola and Aristotle, and presented each subject more fully than his earlier, more elementary textbooks. Finally in *Erotemata dialectices (Questions on Dialectic)* (1547) the dialectic was revised and enlarged to the point where it could be a self-sufficient course, replacing Aristotle altogether. These textbooks included many examples taken from classical literature and the Bible.

In rhetoric Melanchthon's principal innovations were the addition of a fourth genre of oratory (educational, in addition to judicial, deliberative and demonstrative), and the establishment of a simple type of invention for this genre and for 'simple' subjects. This consisted of a small group of questions for the speaker to consider: what is it? what are its parts? what are its causes? what are its effects? which things follow and which oppose? These questions were a selection from the topics, but they can also be seen as a development of the ideas on invention found in the *progymnasmata*, the exercises in short forms of composition which were often used in humanist grammar schools. In later versions he added to the traditional Ciceronian rhetoric syllabus sections on emotional manipulation (summarized from Aristotle), on amplification (based on Erasmus' *De copia*) and on the imitation of Cicero (§2), with particular attention to the theories of prose composition outlined in Cicero's *Orator*.

In dialectic Melanchthon gave particular attention to definition (under which he dealt with the predicables and the categories) and division. As in his rhetoric he introduced an additional but simpler form of invention for easy themes. In the earlier versions this consisted of four topics: definition, causes, parts and effects. By 1547 this became a list of ten questions and had been renamed the method. Method was a topic of considerable interest in the early sixteenth century, on the basis of remarks on the subject by Plato (§§4-5) and Galen (§4), and a reappraisal of Aristotle's *Posterior Analytics* (see Aristotle §§4-6). Melanchthon noticed the connection between method and invention, either through the topics or according to status theory (a technique for determining the key issue at stake in an argument and the best way to argue it) (see Cicero's *On Invention*). His ten questions (what does the word mean? does the thing exist? what is the thing? what are its parts? what is its species? what are its causes? what are its effects? which things are connected to it? what are its cognates? what are its opposites?) represent an amalgamation of the four kinds of question from the second book of Aristotle's *Posterior Analytics*, and a Ciceronian version of the topics. This left a slightly awkward question about the point of the full list of topics, which Melanchthon relegates to the end of his books on dialectic. In 1527 the topics were said to amplify the basic material. In 1547 Melanchthon explained that the method is applied to single words, with topical invention reserved for the proposition. Perhaps the four topics (1527) or the method (1547) were intended to help train beginners, while Melanchthon's basic respect for traditional materials encourages him to include the full list as well. Melanchthon's versions of the topics increase in size in the successive versions of the book. By 1547 they include not only a good deal of material from Agricola's version, but also rules that resemble Boethius' topical maxims (which Agricola rejected). This reflects Melanchthon's eclecticism and the tendency of his dialectic to become more inclusive. By 1547 such strictly scholastic ideas as the theory of supposition have found a place in his dialectic, alongside denunciations of the ancient sceptics and their modes of argument.

Throughout his career Melanchthon insisted on there being connections between rhetoric and dialectic, and on their practical value as guides to reading and composition. He taught manuals of rhetoric and dialectic alongside orations by Cicero or St Paul's letters, so that the precepts could be used to inform reading of the texts, while the texts could illustrate the practical value of the precepts. Melanchthon's published commentaries on Cicero and St Paul make considerable use of rhetoric and dialectic. His major commentary on Romans was entitled *Dispositio orationis in Epistola Pauli ad Romanos (The Disposition of the Oration in St Paul's Epistle to the Romans)* (1530) and devoted itself to the connections between the propositions in that work. In his commentary on Cicero's *Topics*, he analysed a passage from Psalm 1 to explore the similarity between the topics of invention and the figures of rhetoric. This idea goes further than Agricola's analysis of poetic effects in some of his topics entries.

Melanchthon's dialectic textbooks were very influential, going through more than ninety editions in the sixteenth century and becoming required reading in many Protestant German universities, while versions of his rhetoric were printed at least forty times. Many successful textbooks were also composed by his followers, including Thomas Wilson, whose *Arte of Rhetorique* and *Rule of Reason* were the most successful sixteenth-century textbooks of the two subjects in the English language.

3 Ethics

Melanchthon's principal work of moral philosophy was *Philosophiae moralis Epitome (Epitome of Moral Philosophy)* (1538), which he later revised as *Ethicae doctrinae elementorum libri duo (Two Books of the Elements of the Teaching of Ethics)* (1550). Melanchthon creates a space for moral philosophy by making a distinction between God's law and his gospel. Where the gospel is concerned with God's promise to humanity and the forgiveness of sins, the law tells people how they ought to behave in relation to God and other people. He wrote that: 'Moral philosophy is that part of the divine law which teaches about external actions' ([1497-1560] 1963: vol. 16, col. 21). As law, moral philosophy is reliable, but it treats only human external relations, not the relationship between God and the individual. By making clear the primacy of the gospel and allocating a distinct sphere of activity to moral philosophy, Melanchthon both legitimizes teaching the subject and tries to avoid arguments about contradictions between the Bible and philosophy. He produces quotations from scripture to support moral philosophy, and argues that it is useful as part of education, as the basis for human law, that it helps the theologian in interpreting scripture, and that it is a part of the knowledge which gives human beings pleasure.

Melanchthon's approach to moral philosophy is basically Aristotelian (see Aristotelianism, Renaissance §7). Like Aristotle, he sets out by establishing the aim of humankind. In Christian terms this aim is to acknowledge God and take part in his glory. As a result of the Fall, Aristotle was unable to see this, but his idea that the purpose of human life is the exercise of virtue is assimilated by Melanchthon as the aim of external human behaviour. He is even able to accept Aristotle's analysis of virtue as a medium between vices, after a little discussion of the meaning of 'medium'. This contrasts with Luther's hostility to Aristotelian ethics, which he thought had corrupted Christian thought.

As part of his justification of moral philosophy Melanchthon touches on the issue of the freedom of the will. He explains that since philosophy is concerned with behaviour in civil life and not with spiritual issues, it must first be acknowledged that in everyday dealings with other people the will is free, both because scripture says so, and because otherwise there would be no need for laws. He goes on to argue that free will also plays a part in spiritual life, since although no man can feel true remorse or true faith without the help of the Holy Spirit, that help still partly depends on human will.

The list of virtues which Melanchthon discusses seems to have been influenced by Aristotle (for example he gives most space to justice, and he includes friendship), but the actual treatment combines Protestant concerns with the adaptation of Aristotle: there are discussions of the role of the prince in matters of religion, and the religious force of human laws. In contrast to his use of Aristotle, Melanchthon is generally hostile to other ancient schools of philosophy, rejecting the Epicurean position on pleasure and Stoic doctrines on fate and the need to rise above the emotions (see Epicureanism §10; Stoicism §§19-20). He also wrote commentaries on Aristotle's *Ethics* and Cicero's *On Duties (De officiis)*.

4 Psychology and physics

Melanchthon's *Liber de anima (Book on the Soul)* (1540) was intended to be an elementary textbook. As such it was highly successful, going through forty editions and receiving eight commentaries in the sixteenth century. It explicitly avoids ancient and medieval controversies about the interpretation of Aristotle's text, preferring to give a simple exposition of faculty psychology (the theory by which the soul was considered to be divided into three aspects: vegetative, sentient and rational, each having its own range of distinct powers). Scripture takes precedence over philosophy, so for example Melanchthon took for granted the immortality of the individual soul rather than arguing through the implications of Averroes' interpretation of Aristotle and its associated controversies, which were still being argued over in sixteenth-century Italy. At the end of the book he turns away from the classical subject-matter of psychology with a more theological section upholding the freedom of the will (see Aristotelianism, Renaissance §§4-5).

The discussion is conducted in a thoroughly humanist manner, with quotations in Greek, citation of literary texts, and a lengthy argument supporting Cicero's mistaken view (*Tusculan Disputations* I.x.22) that Aristotle's definition of the soul involved reference to *endelecheia* (continuance or eternity) rather than *entelecheia* (actuality) (see Aristotle §17). Melanchthon adds to Aristotle's account of the soul a lengthy discussion of anatomy and physiology (which refers to Vesalius' illustrations of dissections of the human body), a discussion of dreams, and an argument in favour of certainty and against scepticism. His major innovation was to avoid the controversy surrounding the 'possible' and 'agent' intellects by proposing a new, and far simpler, interpretation by which the agent intellect was the faculty of invention (in the rhetorical or dialectical sense) and the possible intellect the faculty of judgment (in the dialectical sense of checking the strength of arguments and putting them in set forms). This idea links his psychology with his dialectic. His work on physics, the *Initia doctrinae physicae (Introduction to Physics)* (1549) is a thoroughly Aristotelian manual, providing an elementary summary which follows the order of the *Physics*, but adding material from other parts of Aristotle's natural philosophy, and a long section on astronomy, according to the Ptolemaic model (see Ptolemy).

Melissus (mid or late 5th century BC)

Melissus was a Greek philosopher from the island of Samos. A second-generation representative of Eleatic metaphysics, he published one work, entitled On Nature or On That-Which-Is, which has been partially reconstructed by editors. It defends a version of Parmenides' monism, but recast with terminology and arguments directly accessible to a readership schooled in the eastern Greek (Ionian) style of physical speculation, as distinct from Parmenides' western Greek background. Although it is uncertain how important Melissus was to his own contemporaries, his prosaic but clear presentation of Eleatic concepts was more widely adopted by later writers than the enigmatic pronouncements of Parmenides.

Melissus argues that that-which-is is: (1) omnitemporal; (2) infinite in extent; (3) one; (4) homogeneous; (5) changeless, that is, without (a) reordering, (b) pain, (c) grief or (d) motion; (6) indivisible; and (7) bodiless. Here (1) - 'it always was what it was, and always will be' - is a departure from Parmenides, who had outlawed past and future in favour of a static present. Likewise (2) contrasts with Parmenides' defence of spatially finite being. The remaining predicates are consonant with Parmenides, although (5)b-c suggest that the being Melissus has in mind is a living one, presumably a deity - an aspect not brought out by Parmenides. Melissus wrote 'If there were many things, they ought to be such as I say the One is' - a remark sometimes thought to have inspired his contemporaries the atomists.

1 Life and work

In his own day, Melissus may have won greater renown as an admiral than as a philosopher. The one firm date in his life is 441 BC, when he led the navy of his native Samos to victory over an Athenian fleet commanded by Pericles. Since his age at the time is unknown, the date of his book might be placed anywhere between 490 and 390 BC. One very suspect source makes his philosophy already known to the Athenian politician Themistocles, who died *c*.462 BC. But the Epicurean Colotes, in a work which after criticizing its principal target Democritus turned the attack onto a further eight philosophers in apparently chronological order, placed Melissus after Socrates, who was active *c*.440-399 BC, a clue which would bring his *floruit* well into the second half of the fifth century - late enough for him to have read Empedocles, Anaxagoras and perhaps even the atomists. The tradition that he studied under Parmenides is not particularly trustworthy, although it cannot be doubted that Parmenides was the dominant influence on his philosophy.

A number of verbatim fragments of his one book have been preserved by Simplicius. They can be pieced together with the help of Simplicius' ancillary paraphrase and another in the Peripatetic treatise *On Melissus, Xenophanes and Gorgias*.

2 Philosophical aims

Melissus' treatise is a methodical defence of Eleatic monism, written in unadorned Ionian prose. The conclusions are by and large Parmenidean, but the arguments are not. There is virtually no sign of Parmenides' most characteristic argument against change - that it would entail not-being, an altogether inapplicable concept (see Parmenides §§2-4). Instead, Melissus relies on the barely controversial premise 'Nothing could ever come to be out of nothing' (fr. 1). Furthermore, whereas Parmenides had in the main inferred each predicate of that-which-is by an independent argument, nearly all Melissus' inferences form a single chain, with each predicate inferred directly from the previous one.

Melissus is not interested in Parmenides' highly refined mode of investigation through the logic of being. He writes as a physical thinker addressing a like-minded audience, and expounds the Eleatic One with arguments appropriate to Ionian cosmology. His title (probably authentic, despite some scholars' hesitation), *On Nature or On That-Which-Is* ['on nature' in Greek is *physis*], in effect announces that this is to be an Eleatic *physics*. His departures from Parmenides, in reverting to ordinary temporal language and in postulating a spatially infinite being, are more symptomatic of this project than of intellectual independence.

3 Temporal and spatial infinity

For the book's beginning we have a probably complete text. It opens as follows: 'It always was what it was, and

always will be. For if it came to be, it is necessary that before it came to be there [or 'it'] was nothing. Well if there [or 'it'] was nothing, nothing could ever come to be out of nothing' (fr. 1). 'Since, then, it did not come to be, it both is and always was and always will be' (fr. 2, beginning).

Unlike Parmenides' highly paradoxical rejection of not-being, Melissus' opening move would be unsurprising to an audience familiar with earlier Ionian cosmologists in the tradition of Anaximander (§2), thinkers whose fundamental tenet had been the permanent existence of an underlying stuff. The commonly assumed causal (rather than ontological) principle 'Nothing could ever come to be out of nothing' was its basis. Equally unsurprising in an Ionian context (see Heraclitus, fr. 30) is Melissus' expression of this permanence in terms of omnitemporality, where Parmenides had chosen to collapse past and future into the present. It is probably misleading to call this a significant philosophical disagreement. Melissus is simply translating Parmenidean thought into the philosophical language which his audience speaks.

As in Parmenides, the rejection of past generation is not followed up with an explicit defence of future imperishability. This is assumed to follow by parity of reasoning. The ground this time would be that 'nothing could perish into nothing'.

In the following part of fragment 2 Melissus moves on from temporal to spatial infinity. (This clear division has been widely missed by scholars who have supposed that the new argument must start at the beginning of fragment 2.): 'And it has no [spatial] beginning or end, but is infinite. For if it had come to be it would have a [spatial] beginning (for it would have begun the process of coming-to-be at some time) and end (for it would have ended the process of coming-to-be at some time). But since it neither began nor ended [the process], and always was and always will be, it has no [spatial] beginning or end'.

The interpretation of this has been much debated. Critics from Aristotle on have detected the fallacious inference 'If *p*, *q*; but not-*p*; therefore not-*q*'. To see why this is unfair, it is crucial to appreciate that, where Parmenides' arguments had evidently addressed an audience accustomed to the concept of a finite universe (see Parmenides §3), Melissus assumes the opposite - that the universe will be infinite unless it can be shown to be otherwise. This is yet another sign of his audience's background in Ionian physics, where the infinity of the universe, prefigured as early as Anaximander, was by Melissus' day enshrined in Anaxagoras' cosmology and on its way to becoming central to atomism (see Anaxagoras §2; Atomism, Ancient.

Melissus' question is: what could have set bounds on that-which-is? If nothing, then it is infinite. Only one thing could have made it finite, and that is a process of generation. Since any generative process would have to be temporally bounded, it could only have produced a spatially finite being. You cannot *create* an infinitely large entity, any more than you can build an infinitely long road, given only that any such process must start at some time (and hence somewhere) and stop at some time (and hence somewhere). Since, therefore, it has already been demonstrated that that-which-is never came to be, there is nothing to limit it spatially, and it becomes infinite by default.

Having demonstrated first its temporal and then its spatial infinity, Melissus adds how the latter is both inferentially dependent on and parallel to the former: 'For what is not *all* would not be able to be *always*' (end of fr. 2). 'But just as it is always, so too it must also always be infinite in magnitude' (fr. 3). 'Nothing is either omnitemporal or infinite if it has a [spatial?] beginning and end' (fr. 4).

The first sentence is particularly obscure. Melissus is perhaps drawing once again on a common assumption of Ionian material monism, that only the underlying stuff of the universe, taken as a whole, is everlasting, while the individual portions of it which constitute animals etc. (*if* there are any, Melissus would add) are temporary. Therefore the entity which Melissus calls everlasting must be the whole of what there is. This, if not a sufficient condition of its being infinite, he clearly regards as a necessary condition.

4 Changeless unity

That-which-is is called 'the One' by Melissus, a new emphasis on unity only weakly prefigured in Parmenides. In fragment 6 Melissus formally infers its unity from its spatial infinity: 'For if there were two they would not be able to be infinite, but would have boundaries in relation to each other'. Oneness here appears to mean uniqueness, and unfortunately it is hard to find any reading of the preceding arguments for its infinity which does not already

assume that there is just one of it. A further objection made by the Peripatetic Eudemus, that the inference depends on its being not merely infinite but infinite in all directions, is less worrying, since the argument for its infinity does indeed imply the latter.

The proof of the next attribute, ‘alike’, that is, homogeneous, survives only in a paraphrase: ‘Being one, it is alike everywhere [or ‘in every way’]. For if it were unlike, there would be a plurality, and no longer one but many’ (*On Melissus, Xenophanes and Gorgias* 974a12-14). Its homogeneity thus follows from its oneness. But whether the preceding arguments have shown it to be ‘one’ in the required sense (= ‘partless’ rather than ‘unique’?) is debatable.

After a brief summary of the results so far (fr. 7.1), there follows a generic argument against change: ‘And it could neither lose anything nor become larger nor be rearranged, nor does it suffer pain or grief. For if any of these happened to it, it would no longer be one. For if it changes, it is necessary that that-which-is is not alike, but that what previously was perishes while that-which-is-not comes to be. So if it were to become changed by a single hair in ten thousand years, it will all perish in the whole of time’.

Formally, this is meant to be an inference from the immediately preceding attribute ‘alike’, in conformity to Melissus’ standard inference pattern (see §2). But this time the likeness has to be invariance over time, not space, and that has not been specifically defended. (The defence might be that variation over time would imply a plurality of temporal parts, bordering on each other and therefore failing to be omnitemporal.) We should perhaps think of the likeness-changelessness inference as dictated by formal considerations, and give primary weight to the more interesting final sentence. This implies a version of the Principle of Plenitude: given infinite time all possibilities are realized. *Any* piecemeal perishing, however nugatory, makes overall perishing a possibility, and therefore a certainty over an infinite timespan - contrary to the earlier demonstration of everlastingness.

Following the generic rejection of change, Melissus adds four arguments against four species of change: reordering, pain, grief and motion (frs 7.3-10). The first three largely reapply the generic objections, but with the added consideration that pain and grief, being weaknesses, are incompatible with everlastingness. Melissus’ concern to deny human forms of suffering to his One has caused surprise. But it must be borne in mind that some Ionian thinkers had already endowed the unitary underlying substance with the characteristics of divinity (see Anaximander §2; Anaximenes §1). If, as suggested, Melissus is working within and correcting that tradition, a later report that he equated his One with God may be well founded.

The refutation of motion can be paraphrased as follows. Since void would be nothing, void clearly does not exist. Therefore that-which-is, lacking any admixture of void, cannot vary in density but is completely full. Therefore it cannot give way at any point. Therefore it cannot (internally) move (frs 7.7-10).

This rejection of void as ‘nothing’ is the nearest Melissus comes to accepting Parmenides’ outlawing of not-being. But he also makes an important advance on Parmenides in rendering explicit the dependence of motion on void.

Two further inferences are recorded. Being motionless, it is indivisible, since division involves motion (fr. 10). And ‘Being one, it must not have [a?] body. If it had bulk, it would have parts and no longer be one’ (fr. 9). The latter is especially puzzling, since the One’s incorporeality would seem to undermine the argument for its immobility on the grounds of ‘fullness’ (that is, solidity). It is likelier that Melissus would be denying that it has *a* body, one with organic parts, by way of objection to anthropomorphic conceptions of divinity. But it is doubtful whether the argument, at least as reported, can support this interpretation.

5 Attack on the senses

In fragment 8, apparently from a separate section of his book, Melissus follows the example set by Parmenides in turning his ontological conclusions against the senses. Since sense perception reports constant change, both between distinct stuffs and between pairs of opposite properties, it cannot be trusted. These many items, if real, would have to obey Melissus’ strictures and be altogether changeless, each of them staying exactly as it seemed when first encountered. In short: ‘If there were many things, they ought to be such as I say the One is’.

6 Influence

This last remark is often conjectured to have inspired early atomism, whose exponents Leucippus and Democritus

(§2) did indeed populate the universe with an infinite plurality of atoms, each internally changeless like a Melissan One. Likewise Melissus' insistence that void is a necessary condition of motion (see §4) may be seen as having helped prompt the atomists' rehabilitation of void.

However, the chronological relation of Leucippus to Melissus remains undetermined. The void-motion connection could as well be one that Melissus learnt from Leucippus as vice versa; and the atomists' introduction of an Eleatic plurality may have needed no impetus from Melissus, just their rehabilitation of Parmenidean not-being in the guise of void, which already implied the separation of Parmenidean being into a plurality of discrete parts. The seductive hypothesis of Melissan influence on the atomists must then remain unproven. Stronger evidence of his public recognition as a philosophical writer in his own day is the fact that his book *On Nature or On That-Which-Is* was evidently a primary target for Gorgias in his *On That-Which-Is-Not or On Nature, a parody of Eleatic Philosophy*, a parody of Eleatic philosophy.

In subsequent generations Melissus never inspired the kind of reverence, or even respect, that Parmenides was accorded. But his generally clear formulations of Eleatic positions are much more widely reflected in later writers, especially Aristotle, than the high-flown obscurities of Parmenides. He can thus be regarded, if not as the driving intellect of Eleatic thought, at least as its leading public voice.

Memory

Memory is central to every way in which we deal with things. One might subsume memory under the category of intellect, since it is our capacity to retain what we sense, enjoy and suffer, and thus to become knowing in our perception and other activities. As intelligent retention, memory cannot be distinguished from our acquisition of skills, habits and customs - our capabilities both for prudence and for deliberate risk. As retention, memory is a vital condition of the formation of language.

Amnesia illustrates dramatically the difference between memory as retention of language and skills, and memory as the power to recollect and to recognize specific things. In amnesia we lose, not our general power of retention, but recall of facts - the prior events of our life, and our power to recognize people and places. Amnesiacs recognize kinds of things. They know it is a wristwatch they are wearing, while unable to recognize it as their own.

This recall of events and facts which enables us to recognize things as our own, is more than just the ability to give correctly an account of them. One might accurately describe some part of one's past inadvertently, or after hypnosis, or by relying on incidental information. Thus, present research on memory both as retention and as recall of specific episodes, attempts to characterize the connection which persists between experience and recall. Neurological or computer models of connectivity owe something to traditional notions of a memory trace, but emphasize also the re-tracing of original memories by later experience and by intervening episodes of recall.

1 History of the interest in memory

It is striking that in two standard compendia of Chinese and of Indian philosophy, there are no entries under memory, remembering, reminiscence or recall. Naturally, there are words used in those cultures which roughly match terms in European languages - any human being will speak of what they did at some time earlier; children begin to speak spontaneously of what they did the day before, and remark with delight or distress at things they have seen earlier. But memory as a philosophical preoccupation is specific to certain cultural periods; memory as our powers of retention is so central to intelligent activity as to be subsumed under intellect.

Within Western philosophy itself, there is no mention of memory in the pre-Socratic fragments. It seems that so long as the poetic history of Homer held sway, memory was not discussed by him or the philosophers. This was not for want of interest in the events of earlier times. Homer aptly and vividly evokes their reality. Then in Plato's Socratic dialogues, while Homeric poetry is attacked as endangering an interest in truth, concern with the past is displaced by a search into memory itself, and Plato's dialogues - his own artful contrivances - are presented as if recollections. Within this new myth of a historical anti-poetic Socrates we learn the philosophical values of truth as against poetry, and of strict recollection against mere fancy about the past.

Plato's Socrates argued initially that all knowledge is recollection. He denied that sensory experience (in the present) produces knowledge, and conjectured that recollection revived knowledge acquired in a life before birth (see Plato §11). Thus not only the Homeric tradition of finding significance in human affairs in a (partly legendary) past is rejected, but also the role of women, those responsible for the child gaining its foundational knowledge, is elided.

In Plato's later *Theaetetus* we find the image of memory as an imprint left in the soul by earlier experience, a trace of what has occurred. In place of Plato's allegory of knowledge as recollection of a state in which knowledge was gained without the impurities of sensory experience we find this more scientific speculation about possible mechanisms of memory, an idea taken up by his student and successor, Aristotle. About eight centuries later these connected concepts of memory and of the past were brought into crisis by the north African Augustine. The present hour consists not only of the present minute, but of past minutes and the minutes to come. In turn, the present minute consists not only of its present second, but of its past seconds and the seconds to come. Thus, successively, the present as an extended period disappears. It remains only as an extensionless cut between the periods of past and future. The picture of present memory as defining the reality of the past is erased (see Augustine §§5, 7).

In the seventeenth century Descartes excepted memory from his radical questioning of the senses, while his notion of instantaneous reasoning was to avoid the reliance of reason on memory in any case. That all understanding of

the past rested on personal memory remained unquestioned by Locke and Hume, and yet all arguments for the validity of memory assumed what they tried to prove. While Locke took common sense as a sufficient reply, Hume drew radically sceptical conclusions. Kant tried to show that the forms of knowledge cast into doubt by Hume were conditions of any coherent experience. Memory, as retaining an awareness of what something is like over some finite period of time, for instance, is such a condition of intelligible experience.

This emphasis on the mind's contribution to the order of things led, however, to an idealism in which the mind knows, not the world itself, but its own forms of representation. Thus the sceptical empiricist tradition set in motion by Descartes, while shaken, was not overturned. The sceptical tradition was empiricist in locating the sources of knowledge within the elements of experience. The emphasis on this experience made it seem that experience itself rather than what we experienced was the primary object of knowledge. Towards the end of the nineteenth century Husserl, inspired by Frege, Brentano and Meinong, created a comprehensive alternative to empiricism - a phenomenology of experience as revealing, not itself but its objects. This phenomenology attempted an unprejudiced study of experience, including memory, as ways in which we grasp the world itself (see Phenomenology, epistemic issues in).

Husserl's enquiries led him finally to think of the human body itself, acting as part of a socially significant world, as the centre of conscious experience. Remembering is one of the activities by which we hold bodily sway in the world. This approach was developed by Heidegger, Sartre and Merleau-Ponty. Alternatives to mind-centred empiricism were also developed during much the same period within analytical philosophy by Wittgenstein, Ryle and J.L. Austin.

2 Contemporary work: retention, imagery and feeling

Retention and recollection. Those who suffer from amnesia, knowing neither who they are, nor any event of their previous lives, retain most of their know-how intact. An amnesiac victim might join in a philosophical discussion, only learning from the impression made on others that they must have practised philosophy during that lost section of their lives. No one is surprised that an amnesiac can speak their mother tongue, nor that they can walk, sing and bargain. Thus, memory as retention of skills is different from the recollection of events, neighbourhoods, smells and sounds.

Imagery. As practised by Wittgenstein, Ryle and J.L. Austin, philosophy broke away from an entrancement with memory as a present image within which one must discern pastness and valid indications of the past. Much of what we call remembering has little to do with the possession of imagery. And, though some events come back to us in flashes of imagery, more is required before one remembers anything coherently. On the other hand, aware of little but the buzz of our conversation we may be recalling things with great accuracy. Similarly, depending on no prior image of the tune, one may hum a melody heard at a concert the previous evening. The recall may leave us with images; images of the past need not have provided the recall. Unable to remember someone's expression, we might mimic it. A flash of an image *may* facilitate that mimesis but, equally, the effort of producing the facial expression may be what lets loose our imagery. Thus images, sometimes central to remembering, may be more product than cause of recall (see Imagery).

Feelings. Though displaced from the centre of our picture of memory, imagery remains strongly associated with our elemental feelings about this power to recall. Perhaps this is because of the importance to us of certain intimate forms of remembering, particularly reminiscing and reliving, which vitally involve either imagery or emotion. True, reliving the past in animated conversation may involve little imagery of it. Yet, in the absence of specific imagery, our feelings - some shadow or reanimation of how we felt at the time, are essential to our reliving the past rather than simply reporting it from memory. These feelings we have in reliving prior experiences themselves have something of the quality of images. So, while memory does not consist in a memory image, the existence of a complex interplay of image and affect in the processes of recall is important to the cluster of ideas brought together under memory.

The dead past. To undergo an experience of recall is to be subject to the return of the past - only a metaphor, yet irreplaceable in a philosophy of memory. (In French, the principal verbs of recall are *se souvenir* - to bring oneself under (the past), and *se rappeller* - to call (the past) back to oneself.) Yet, remembering as bringing back what happened, or as reliving the past, encounters an impasse - accounts of memory are haunted by the notion of the

past as dead, as if requiring memory's miracle of resurrection. The desire to remember thus encounters the limits met by mourning - itself a principal paradigm and emblem for memory in general. As memory would revive the events known to be past, in mourning the impulse is to address, as if to recall, the one known to have died.

3 Contemporary work: causal connections and traces

The initial conceptual analysis of the language of memory concentrated on the everyday contexts in which we learn and use our language of memory, and centred on remembering as successful present performance. But the picture which emerged of remembering as simply getting it right about our own past is unsatisfactory. After all, we may describe events from early childhood, not from memory of them, but from having been told by others. Different aspects of our past, in contrast, may come to mind from our own recall. No one else might have been in a position to tell us of certain details which subsequent evidence corroborates. Hence, to remember something is not simply to represent it correctly later on. Nor can memory be defined by the idea of (Hume's) lively belief about one's past. Sometimes we are recalling something when engaged in what we think of as pure imagination. We might intend to write a fictional story, and others may point out that it matches, incident for incident, some episode of which, hitherto, no one had informed us.

Remembering cannot be defined, either, as the representation of one's past without the need for prompting. After all, quite without assistance, we might merely invent something which, coincidentally, did happen. Conversely, we may not remember something and then, upon being prompted, remember the event for ourselves. A reference to some connection between the past event and the present recall seems to be needed - someone suffering amnesia, but hypnotized to recount a traffic accident which, coincidentally, did happen to them is not thereby remembering it. If they now recount something, not in any way because it happened to them, but simply because of the hypnotist's suggestion, they are remembering only what the hypnotist told them.

This idea of a causal connection between the event and its subsequent recall involves its own difficulties, however. The hypnotist might think of the story only because they recall hearing about the accident from the subject before the subject suffered amnesia. So the subject's original experience of the accident plays a crucial causal role in the subject's now coming to recount the event. The causal connection requires more exact definition. The subject's original experience is causally relevant only for the hypnotist's suggesting the story to them subsequently. Assuming that the hypnosis does not actually revive the memory of the accident, it is causally irrelevant to the subject's accepting the story upon its being suggested to them by the hypnotist.

Alas, complication follows complication. It is easy to imagine that the trauma of the accident might have made the victim more highly suggestible to hypnotists' stories about accidents. So the subject's having been in the accident they subsequently describe might still be relevant to their acceptance of the hypnotist's suggestion, and not only relevant to the suggestion being made to them. It seems one must reinvoke the ancient idea of a memory trace which encodes the information the person gains from an experience. Only where there is an activation of such a trace is there the highly specific causal connection required for true remembering. Such an idea appeals both to common sense and to some contemporary scientific theories of how both general information and specific events might be stored - cortically, and also as conditioned reflexes, making possible muscle memory, as musicians and sports professionals speak of it.

This idea of memory is not universally accepted. Not enough is known about the physiological processes required for the memory of specific events, to say that we can insist upon the presence of such a strict trace. In reply, it will be insisted that while memory may be highly dispersed in alternative neural networks rather than encoded in specific brain cells, it is hard to imagine any alternative to a neural, or neuro-muscular process which would preserve the highly specific information about individual events which makes it possible for us to recall them with all the sensual and emotive feel which they commonly carry.

It has also been objected to such a causal analysis of remembering that memory is a power or disposition to recount things about one's past. Is it not absurd to suggest that some past event should continuously cause the continuation of such a power of recall? Is this not like saying that the capacity of one's living room curtains to keep their colour, day in, day out, is continually held in place by their originally having been dyed? In reply, a causal theorist will point out that it is not the power of recall which is continually upheld by an event in the past. What is required, more simply, is that the trace established by the event remembered should encode all the

information genuinely recalled, and that if prompting is necessary (as normally it is), this prompting should activate that encoding trace.

4 Contemporary work: challenges to fixed ideas of present and past

These approaches, both through everyday concepts and by speculative scientific hypothesis, take for granted memory as reviving an already given past. The phenomenology of Sartre and Merleau-Ponty, too, takes the past as real in itself, not to be reduced in Augustinian fashion to the process of recollection. Nevertheless, their work emphasizes how much what we call past and present owe each other. The past does not so innocently create memories which then we deem to be valid. Perhaps half-consciously, we make nothing of aspects of our past in order to make something of other aspects. We might create a favourable past or, alternatively, one which embodies a harsh vision of our lives. What we remember is not entirely accidental. How we remember and what we recall partially constitutes our present and, conversely, what we countenance as part of our present bears on what we are prepared to recall.

The themes of memory are recalled in a classical enigma. When the present was present, it could not be remembered. Now it is past, its presence is only in recall. This presence in recall cannot be the presence it had when first it occurred. It is in this sense that remembering is, in Derrida's phrase, the raising up of 'a past that was never present'.

Memory, epistemology of

Memory appears to preserve knowledge, but there are epistemic questions about how this could be. Memory is fallible, and empirical research has identified various ways in which people systematically misremember. Even wholesale error seems possible: Russell (1927) proposed that it is logically possible for the world to have sprung into existence five minutes ago, complete with spurious ostensible memories of earlier times. In light of such possibilities, some sceptics argue that memory cannot yield knowledge.

Assuming that memory provides knowledge, there are serious epistemic issues about how it does this. For instance, does some introspectible quality of remembering provide distinctive evidence for what is remembered, or is it some other feature of memory that secures the epistemic justification needed for knowledge? How readily recollectible must a proposition be in order for it to be known while it is not being recalled? Does a full retention in memory of a previous basis for knowing something assure continuing knowledge of it? Does forgetting an original basis for knowing without replacing it imply a loss of knowledge?

1 Memory and traditional epistemic issues

Epistemic controversies about matters specific to memory are comparatively rare. There are two apparent reasons for this. One is that remembering is a source of reasons for belief with approximately the same problems and prospects as sensory perception (see Perception, epistemic issues in). The two processes share the salient features of being conscious, cognitive episodes that prompt new beliefs without apparent inference. Of the two, perception seems the more promising source of justification. This is principally because conscious sensory characteristics are clearly involved in ordinary sensory perception. They provide something that might confer justification on some resulting perceptual beliefs, though it is problematic how sensory characteristics could justify beliefs. In contrast to the perceptual case, no conscious qualities are clearly distinctive of recollective events. There may be less of a basis on which to explain how memory can furnish justification and knowledge. Thus, the outcome of investigations of the epistemic properties of perception is plausibly thought to carry over to the case of memory, with memory perhaps turning out to have weaker versions of the same epistemic capacities.

A second reason for the relative paucity of epistemic work on memory may be the prevalence in epistemology of disputes about scepticism. In virtually all sceptical controversies, remembering plays at most a derivative epistemic role. Memory on its own serves as a means of knowledge preservation, not knowledge acquisition. The fundamental sceptical issues concern whether justified belief or knowledge can be had in the first place. For instance, if some sceptical argument shows that we can have neither perceptual knowledge nor justified perceptual belief, then no important epistemic question about recalling perceptual beliefs seems to remain. If on the other hand scepticism about some such category of knowledge is refuted, then memory offers only the prospect of retention of knowledge in that category. This is not to say that knowledge retention is unimportant. Retaining nothing, we could know only the facts that we could learn entirely in a moment. But retention seems less epistemically fundamental than do capacities that arguably enable us to acquire new knowledge.

Some sceptical challenges have specifically addressed memory knowledge. The sceptical arguments have generally charged that something about the vulnerability of memory to error shows it not to be a source of reasons sufficiently strong to provide knowledge. But again, memory is not unique in the relevant epistemic respects. Assessments of analogous sceptical arguments concerning sensory perception carry over to this sort of attack on memory knowledge. The familiar mechanisms of deception such as ordinary sorts of error, the evil demon of Descartes and the illusory stimulations of electrodes, are capable of producing as pervasive and deceptive a replication of veridical experiences in the case of sensory experiences as in the case of ostensible memories. Anti-sceptical responses typically deny that such a deception is genuinely possible, or that its possibility shows that we lack knowledge (see Scepticism). These denials have the same merits whether the argument is aimed at knowledge by perception or knowledge by recollection. Although memory knowledge is one of the most important applications of sceptical reasoning, memory does not raise any distinctive basic sceptical issues.

2 An epistemic problem specially involving memory retention

One epistemic problem of considerable interest does essentially involve the capacity of memory to preserve

knowledge. Suppose that, at noon, Smith knows that Jones is smiling. Smith has reasons that are sufficient for him to know this, including clearly seeing Jones smile. At dusk Smith acquires compelling new evidence to the effect that Jones did not smile at noon, receiving sworn testimony from Robertson, a universally acknowledged pillar of integrity. In an honest error, Robertson sincerely and convincingly testifies that Jones has a double who stood in for Jones at noon. It seems plain that as a result of hearing this testimony Smith no longer knows that Jones smiled at noon. This can be puzzling. For one thing, at dusk Smith might perfectly recall his noontime reasons for believing that Jones smiled at noon. If those reasons were adequate for Smith to know this fact at noon, how can exactly the same reasons be inadequate later?

Also puzzling is the fact that at dusk Smith seems to possess a cogent argument for regarding Robinson’s testimony as misleading. Prior to hearing the testimony, Smith unproblematically remembers and continues to know that Jones smiled at noon. This appears to enable Smith to know by inference that any evidence against Jones having smiled at noon is evidence against a truth, and hence misleading. But even if this inference is fresh in Smith’s mind when he hears Robinson’s testimony, at that point Smith would be unreasonable to regard Robertson’s testimony as misleading. Yet why would this attitude be unreasonable, given the apparent cogency of Smith’s argument for it?

Credible answers to these questions will not deny that we ever fully remember our previous reasons for holding some belief. A more promising approach is suggested by a careful look at the structure of epistemic support for a belief. We should observe that conspicuous positive evidence for a proposition cannot by itself justify believing the proposition. Epistemic justification is more holistic than that. In particular, at noon Smith’s justified belief that Jones was then smiling was supported, not merely by Smith’s seeing Jones smile, but also by perceptual indications and background information that argued that the situation was normal. These indications importantly include the lack of any clue of a deception. It is only this sort of comprehensive body of relevant considerations that can epistemically justify a belief. Anything less may fail to take account of pertinent information (see Knowledge, defeasibility theory of).

This structural feature of justification makes it clear that once Smith has new relevant evidence, even a perfect recollection of his previous evidence about Jones at noon does not guarantee that the belief that Jones smiled at noon continues to be justified. At dusk Smith becomes aware of a strong indication that he was deceived at noon. As a result, the new totality of his evidence does not justify the belief that Jones smiled at noon. Such changes in evidence show why retaining a previous basis for knowing does not entail continuing to know.

Similar considerations explain why Smith cannot reasonably regard Robinson’s testimony as misleading once he hears it. Smith possesses a cogent argument that such evidence is misleading only when his evidence on balance supports that conclusion. Otherwise his evidence casts doubt on the conjunction of the argument’s premises. Until Smith hears Robinson’s testimony, what Smith retains from noon supports without challenge an argument for the conclusion that any evidence against Jones having smiled at noon is misleading. Once Smith hears Robinson’s testimony however, any such argument is undercut. Smith’s evidence may still include all that previously supported the conclusion. But now his evidence also includes his hearing of testimony which spoils that support. The premise asserting that Jones did smile at noon is essential to his justifiably inferring that contrary evidence is misleading. When Smith has heard the testimony, this premise ceases to be supported by the entirety of his pertinent considerations. Smith then has no cogent argument for regarding the testimony as misleading.

Epistemic justification for a belief at a time is constituted only by the totality of relevant considerations possessed at the time. Such a totality can mislead by a deceptive expansion. The justification needed for knowledge thus is holistic and transitory. These properties of justification serve to dispel the mystery of how someone might clearly remember his whole basis for knowing a proposition and for accurately classifying all evidence against it as misleading, and yet be straightaway misled by just such evidence and no longer know the proposition to be true.

3 An epistemic problem specially involving memory loss

Someone might come to know the date of the Battle of Waterloo by reading it in a clearly reliable text. Years later the person may continue to believe that the date is 1815, while entirely forgetting the source of this belief and without receiving any subsequent corroboration of that date. Does thus forgetting imply that the knowledge is lost? If so, then it seems that we cease to know most of what we recall, however securely we first came to believe it,

since it is relatively rare for us to retain our original justification for beliefs not recently acquired. Yet if we do continue to know beliefs of forgotten justifying origins, then it seems that we must somehow manage to know them while lacking justification for them. Each of these alternatives is implausible.

An attractive response to this problem occupies a middle ground. It holds that some retained beliefs whose original justification has been forgotten and which are subject to no new doubts are still known, others not. The difference is made by the facts about how currently reasonable to the person is the proposition that continues to be believed. Retention of the original evidence is not required if one has indications that a reliable memory is operative in sustaining the belief. For instance, where the belief is accompanied by an impression of having some reputable source or other for it, and an impression of having often confirmed and seldom disconfirmed the beliefs that thus seem trustworthy, those impressions help to constitute a current justification for the belief. Where someone has nothing more on behalf of a belief than a sense that the proposition was assertively conveyed at some point, perhaps in fiction or even in a dream, the proposition will not be currently believed reasonably enough to be known.

This is an elaboration and application of the appealing view that a reliable memory is what preserves knowledge. The view tells us that we do not continue to know merely by having a recollective impression of a factual proposition that we once knew and to which we now have no substantial objection. Only those of our recollections that are evidently trustworthy can sustain our knowledge of such propositions.

Mencius (4th century BC)

Mencius (Mengzi) was a Chinese Confucian philosopher, best known for his claim that human nature is good. He is probably the single most influential philosopher in the Chinese tradition, in that an interpretation of his thought became the basis of the civil service examinations in China in the fourteenth century and remained so for almost 600 years. The primary source for his thought is the collection of his sayings, debates and discussions known as the Mengzi.

Mencius (known in Chinese as Mengzi (Master Meng) or by his full name, Meng Ke) was born early in the fourth century BC in the state of Zou, now part of Shandong Province. Towards the end of that century he travelled from state to state, seeking a ruler who would put his philosophy into practice, and briefly served as a minister in the state of Qi. The collection of his sayings, debates and discussions is known simply as the *Mengzi*. It was compiled either by Mencius himself or by his disciples soon after his death.

Mencius saw his main intellectual task as defending the doctrines of Confucius against those of the egoist Yang Zhu and the universalistic consequentialist Mozi. In order to do this, he developed a novel and detailed theory of human nature which went beyond anything Confucius had said.

Mencius' claim that human nature is good has been given different interpretations (see Xing). He clearly thought that humans innately have active but incipient tendencies toward virtue, which he describes, using an agricultural metaphor, as sprouts. Each sprout corresponds to one of his four cardinal virtues, and each virtue has an emotion or attitude that is characteristic of it: benevolence is characterized by compassion, righteousness by shame and disdain, wisdom by approval and disapproval, and ritual propriety by either respect or deference. In a famous example, Mencius says that our sprout of benevolence manifests itself in a spontaneous feeling of 'alarm and compassion' when we 'suddenly' see a child about to fall into a well (*Mengzi* 2A6). This same virtue shows itself in one's compassion for a suffering animal, one's service to and love of one's parents and the disinterested concern of virtuous rulers for their subjects.

Righteousness is similarly complicated, manifesting itself in such things as a beggar refusing to accept a handout given with contempt, a wife and concubine being ashamed of their husband's humiliation of himself to obtain luxuries, a chariot driver being ashamed to cheat in a ritual hunt, a person refusing to accept contemptuous forms of address, disdaining to serve base rulers, and obeying and respecting one's elder brother. One passage (*Mengzi* 5A9) suggests that a wise person is a good judge of the character of others, recognizes what is base and avoids it, is a prudent and perceptive judge of policy and a good administrator. Another passage (4A27) describes wisdom as understanding and being committed to benevolence and righteousness. Mencius does not clearly distinguish the virtue of ritual propriety, although it seems to be related to righteousness.

Neo-Confucian philosophers (see Neo-Confucian philosophy) regarded the four sprouts as fully developed virtues whose operation was impeded (in the uncultivated individual) by selfish desires. However, it is more likely that Mencius thought the sprouts were only incipient virtues, which must be cultivated so that they develop into full virtues (see Self-cultivation in Chinese philosophy). That is, we must 'extend' the reactions of the sprouts from the situations in which we already have them to relevantly similar situations in which we should, but do not yet, have them. Mencius seems to advocate several methods for achieving extension, including 'concentration', which probably includes the reflective and joyful exercise of the sprouts. He also taught his students through the study of poetry and 'case studies' of the actions of sages.

Mencius presents what is recognizable as a virtue ethic, but one that is importantly different in terms of its conception of flourishing, its cardinal virtues and its theory of ethical cultivation from classic Western examples such as those of Aristotle and Thomas Aquinas (see Virtue ethics). Like other virtue ethicists, Mencius regards ethics as objective, but eschews decision procedures based upon either rules or the weighing of utility and stresses the context-sensitivity of virtuous responses. As a Confucian, Mencius holds that virtuous individuals will have compassion for all humans, but he also thinks we have special obligations to, and should have greater concern for, those tied to us by particular bonds, including kinship. Mencius is also typically Confucian in his emphasis upon learning from tradition, and in his belief that the virtues first manifest themselves in the family.

In terms of style, Mencius prefers to focus on the specific and the concrete. For example, Mencius explores virtues and their semblances, not through a Socratic search for definitions but through contrasting concrete examples (for examples, *Mengzi* 2A2; 7B37). Furthermore, what he says is geared to the understanding and needs of his interlocutors on particular occasions. So, for instance, he may be oversimplifying his view of self-cultivation for his audience in *Mengzi* 6B2. However, careful study of the *Mengzi* suggests that underlying his concrete comments on specific occasions is a deep and systematic ethical view.

Mendelssohn, Moses (1729-86)

A Jewish disciple of Leibniz and Wolff, Mendelssohn strove throughout his life to uphold and strengthen their rationalist metaphysics while sustaining his ancestral religion. His most important philosophic task, as he saw it, was to refine and render more persuasive the philosophical proofs for the existence of God, providence and immortality. His major divergence from Leibniz was in stressing that 'the best of all possible worlds', which God had created, was in fact more hospitable to human beings than Leibniz had supposed. Towards the end of his life, the irrationalism of Jacobi and the critical philosophy of Kant shook Mendelssohn's faith in the demonstrability of the fundamental metaphysical precepts, but not his confidence in their truth. They would have to be sustained by 'common sense', he reasoned, until future philosophers succeeded in restoring metaphysics to its former glory. While accepting Wolff's teleological understanding of human nature and natural law, Mendelssohn placed far greater value on human freedom and outlined a political philosophy that protected liberty of conscience. His philosophic defence of his own religion stressed that Judaism is not a 'revealed religion' demanding acceptance of particular dogmas but a 'revealed legislation' requiring the performance of particular actions. The object of this divine and still valid legislation, he suggested, was often to counteract forces that might otherwise subvert the natural religion entrusted to us by reason. To resolve the tension between his own political liberalism and the Bible's endorsement of religious coercion, Mendelssohn argued that contemporary Judaism, at any rate, no longer acknowledges any person's authority to compel others to perform religious acts.

1 Metaphysics/natural theology

Affectionately called 'the German Socrates' by European admirers, and hailed by some of his Jewish disciples as a modern Maimonides, Moses Mendelssohn (born Dessau, died Berlin), despite his hunchback, cut a towering figure in his generation. Emerging from the ghetto with a solid command of traditional Jewish learning and a wide knowledge of medieval Jewish philosophy, he independently learned ancient and modern European languages, literature and philosophy. In an astonishingly short time he became an important cultural critic and went on to produce notable contributions to German philosophy, especially in metaphysics, ethics and political theory. Unlike Spinoza, the only prior Jewish thinker of modern times to have had a major impact on European thought, Mendelssohn retained his affiliation with Judaism. He actively promoted and fostered modernization within the Jewish community and spoke out forcefully and effectively in governmental and intellectual fora for the bestowal of equal civil rights on Jews. Challenged by adversaries and well-intentioned 'friends' to explain his seemingly unjustifiable loyalty to an outmoded religion, Mendelssohn wrote some of the seminal works of modern Jewish philosophy.

Mendelssohn made almost no claim to originality in metaphysics. He described himself as little more than an exponent of the teachings of the Leibniz/Wolffian school, perhaps lending a more felicitous or up-to-date expression to the affirmations of God's existence and providence and human immortality that had been propounded by Leibniz and Wolff and their disciples. Here and there, however, he admitted modestly that he was providing a new version of an old argument or even saying something that had not been said before.

Mendelssohn made his reputation and set out his basic metaphysical stance in his *Abhandlung über die Evidenz in metaphysischen Wissenschaften (Treatise on Evidence in Metaphysical Knowledge)*, an essay that took first prize in a competition sponsored by the Royal Academy in Berlin in 1763; Immanuel Kant received an honourable mention. The Academy's question was whether 'the truths of metaphysics in general, and the first principles of natural theology and morality in particular' can be shown to be as securely established as those of mathematics. Mendelssohn answered that such principles 'are capable of the same certainty' but are by no means as easily grasped. After discussing the obstacles to such comprehension, he went on to offer cosmological and ontological proofs for the existence of God. He sought to give the ontological argument an 'easier turn' by reversing its usual course and arguing first for the impossibility of God's nonexistence and then against the notion that the most perfect being would enjoy a merely possible existence.

Following Leibniz, Mendelssohn argued in a number of writings that the combination of divine goodness and greatness known as providence brings into being 'the best of all possible worlds'. He was certainly aware of the abundance of evil and injustice in the world. But he found that the good outweighed the evil, and indeed that the

quantity of evil was less than Leibniz himself had supposed. For Mendelssohn joined with other, later representatives of the *Aufklärung* in rejecting the Christian dogma, accepted by Leibniz, that most human beings are destined for eternal damnation. This idea, so much at odds with Leibniz's recognition that the perfection and happiness of rational creatures are critical in God's design, was, he wrote, a notion of which 'neither our reason nor our religion knows anything' (see Providence; Evil, problem of).

What reason teaches about the afterlife is, according to Mendelssohn, altogether consolatory. This view emerges most clearly in what was probably his most famous work, a philosophical dialogue entitled *Phädon, oder über die Unsterblichkeit der Seele (Phaedo, or on the Immortality of the Soul)* (1767). Borrowing from Plato the title and the setting, in Socrates' jail cell, Mendelssohn used the condemned philosopher as the mouthpiece for an argument he had admittedly derived from his own recent predecessors, including such *Aufklärer* as the natural theologian Hermann Samuel Reimarus and the liberal Protestant theologian Johann Joachim Spalding. 'Is it consistent', Mendelssohn's Socrates asks, 'with the Supreme Wisdom to produce a world in order to make the happiness of the creatures inhabiting it arise from the contemplation of its wonders and a moment later deprive them of the capacity for contemplation and happiness?' Pursuing the idea of divine goodness to its logical conclusion, Mendelssohn reasoned that the afterlife must be the arena in which the world's injustices are rectified and *all* rational creatures continue to progress towards ever higher perfection and happiness.

Going beyond his rhetorical question and other arguments of similar provenance, Mendelssohn proudly offered what he saw as an original argument for immortality, a 'proof from the harmony of our duties and rights': An individual who believed that death marked the end of his existence would find that his natural right to preserve his own life at all costs would conflict at times with the state's demand that he be prepared to lay down his life for the common good. But such a conflict can have no objective warrant. For in the mind of God, 'all the duties and rights of a moral entity are in the most perfect harmony'. Since the state's right to call for the supreme sacrifice is irrefutable, it is evident, Mendelssohn concludes, that the human soul does not die with the body.

In time Mendelssohn himself came to see weaknesses at many points in the philosophical structure he had upheld. Confronted, toward the end of his life, by the irrationalism of F.H. Jacobi and by the new critical philosophy of Immanuel Kant, whom he called the 'all-crusher', he felt compelled to acknowledge the insufficiency of rationalistic metaphysics. In his fullest exposition of the philosophy he had set forth, *Morgenstunden, oder Vorlesungen über das Dasein Gottes (Morning Hours, or Lectures on the Existence of God)* (1785), he sorrowfully ceased to reaffirm its irrefutable truth.

Yet, whatever speculative reason might seem to teach, he now argued, common sense still sufficed to orient people and guide them along the path to the most important truths. Just what Mendelssohn meant by common sense has been a subject of much dispute, both among his contemporaries such as Thomas Wizenmann and Kant himself and among modern scholars. But, however he conceived of this faculty, it is clear that he expected our reliance on it to be temporary. For, in the 'cyclical course of things', providence would cause new thinkers to arise who would restore metaphysics to its former glory.

2 Moral and political philosophy

Following Wolff, Mendelssohn affirmed that the fundamental moral imperative is a natural law obliging all rational beings to promote their own perfection and that of others. Unlike Wolff, he did not elaborate all the ramifications of this natural law. But he clearly saw perfection in much the same terms as Wolff, as an unending process of physical, moral and intellectual development, leading naturally to the increase of human happiness.

In sharp contrast to Wolff, Mendelssohn regarded liberty as an indispensable precondition of the pursuit of moral and intellectual perfection. Only a free person, he argued, can achieve moral perfection. For virtue is the result of struggle, self-overcoming and sacrifice, and these must be freely chosen. Intellectual perfection, too, can be attained only by one who is free to err. So, in place of Wolff's tutelary state, Mendelssohn developed a contractarian polity that left individuals largely free to define their own goals. Insisting above all on the inalienable liberty of conscience, he decried any state attempt to impose specific religious behaviour or to discriminate against members of a minority faith. While Mendelssohn's liberalism clearly flowed from his commitment to liberty itself, it was no doubt also informed by his concern for the situation of his fellow Jews, whom he ardently wished to see relieved of a degraded political and social status.

3 Philosophy of Judaism

Mendelssohn faced fewer difficulties in reconciling his Leibniz-Wolffian views with his Judaism than his mentors or their disciples had confronted in reconciling their philosophical views with Christianity. Because he saw little conflict between philosophy and Judaism and because his own position as the first Jew to be accepted by the intellectuals in a fundamentally intolerant society was precarious, he initially refrained from explaining to the general public his continued adherence to his ancestral religion. But he was by no means oblivious to the challenges that Enlightenment scepticism posed to all believers in revealed religions. Nor was he immune to attack. In response to repeated demands from critics that he account for his irrational adherence to Judaism, he wrote his celebrated treatise *Jerusalem* (1783). Subtitled *Über religiöse Macht und Judentum* (On Religious Power and Judaism), *Jerusalem* responds to August Friedrich Cranz's charge that the religious coercion of recalcitrant Jews countenanced in Judaism is blatantly incompatible with Mendelssohn's own political liberalism. In responding to this charge, Mendelssohn proceeded beyond the call of his immediate duty and outlined a general philosophy of Judaism.

Viewed against the backdrop of medieval Jewish philosophy, Mendelssohn's account contains both familiar and unfamiliar elements. Following in the footsteps of Saadiah Gaon, Judah Halevi and Maimonides (and seemingly ignoring the criticisms of Spinoza and various sceptics) he maintained that God's revelation at Sinai was an amply attested historical fact (see Saadiah Gaon; Halevi, Judah; Maimonides, M.). What God disclosed to the people of Israel, Mendelssohn held, was not a 'revealed religion' commanding the acceptance of particular dogmas but a 'revealed legislation' requiring the performance of particular actions. The Israelites at Sinai had already acquired, by unaided reason, a knowledge of the universal religion of humankind. What they learned from revelation was a set of God-given duties. Noting the broad range of these duties and the manifold aspects of life encompassed by them, Mendelssohn reflected at length on the so-called 'ceremonial law', problematized at least since the earliest days of the Christian critique of Judaism. This body of obligations, he reasoned, seems to be intended to combat idolatrous tendencies by ordaining actions that perpetually bring to mind the fundamental truths of natural religion. Observance of these divinely ordained regulations allowed Jews to maintain their grasp of true religion and so to serve as a salutary example to the other peoples of the earth (see Halakhah).

In keeping with the tenets of traditional Judaism, Mendelssohn insisted that the Bible's revealed legislation remained in force perpetually, subject only to such modifications as the changes of time and circumstance rendered advisable. But he parted company with tradition in arguing that the Roman destruction of the Temple in Jerusalem had transformed Jewish law from a corpus of communally enforceable obligations into a code which only the individual Jew had the right to impose on himself or herself. This unprecedented claim parried the charge of illiberalism. Whether it represents a reluctant and merely tactical concession to liberalism, as some have argued, or whether it reflects Mendelssohn's true convictions, as is more commonly believed, it was clearly the only means that Mendelssohn could find to render modern Judaism fully compatible with political liberalism.

Mental causation

Both folk and scientific psychology assume that mental events and properties participate in causal relations. However, considerations involving the causal completeness of physics and the apparent non-reducibility of mental phenomena to physical phenomena have challenged these assumptions. In the case of mental events *(such as someone's thinking about Vienna), one proposal has been simply to identify not* 'types' *(or classes) of mental events with* types *of physical events, but merely individual* 'token' *mental events with* token *physical ones, one by one (your and my thinking about Vienna may be 'realized' by different type physical states).*

The role of mental properties *(such as 'being about Vienna') in causation is more problematic. Properties are widely thought to have three features that seem to render them causally irrelevant: (1) they are 'multiply-realizable' (they can be realized in an indefinite variety of substances); (2) many of them seem not to supervene on neurophysiological properties (differences in mental properties do not always depend merely on differences in neurophysiological ones, but upon relations people bear to things outside their skin); and (3) many of them (for example, 'being painful') seem inherently 'subjective' in a way that no objective physical properties seem to be. All of these issues are complicated by the fact that there is no consensus concerning the nature of causal relevance for properties in general.*

1 The problem

Mental causation is central both to our conception of ourselves as thinking and experiencing agents, and to some of the most promising theories of our behaviour. We ordinarily explain, for example, someone's drinking water by citing their thirst and their belief that water would quench it.

Despite the central place of mental causation in both folk and scientific psychology there is a long philosophical tradition that is sceptical about it. This scepticism is based on the apparent scientific intractability of intentionality and consciousness (see Consciousness; Intentionality). Intentionality is the property of mental states whereby they are 'about' things, and can be true or false. For example, the thought that the cat is crying is about the cat and represents it (truly or falsely) as crying. Consciousness involves further subjective and phenomenal properties, such as the taste of beer or the awfulness of pain. It has seemed to some philosophers that it is impossible to fit intentionality and consciousness within the causal order disclosed by physics and biology, and this has led some to the conclusion that there is no genuine mental causation.

2 Cartesian dualism

The *locus classicus* for the problems of mental causation is Cartesian philosophy. Descartes held that mental events and states are distinct from physical events and states: the latter involve changes in the properties (especially spatial properties) of extended bodies, while the former involve changes in the properties (especially properties involving thought) of non-extended mental substance (see Descartes, R. §8; Dualism). He further held that these two kinds of events interact causally. In fact, Descartes thought that mental causes are required to explain linguistic and mathematical behaviour since they exhibit a kind of novelty that he believed could not be accounted for solely in terms of physical causes.

There are many difficulties with Descartes' position, but two are most relevant to our topic. One is that he provided no account of how mental-physical (or mental-mental) causation occurs. He hypothesized that the interaction between mental and bodily events takes place in the pineal gland. While this localizes mental-physical causation, it says nothing about why or how various types of mental states cause, or are caused by, various types of mental or physical states. These connections are posited as basic causal links. But it seems implausible that anything as complicated as mental events should be linked to physical events by basic causal relations.

The second problem is that, contrary to Descartes' view, it is now widely believed that every physical event can be accounted for solely in terms of antecedent physical events (up to whatever objective indeterminism obtains generally) (see Materialism in the philosophy of mind). So, for example, if Alma raises her hand, that movement can be accounted for causally, at least in principle, in terms of prior neurophysiological and other physical events. Alma's conscious decision to raise her hand, if distinct from these physical events, either casually overdetermines the movement or is *epiphenomenal* with respect to it (see Epiphenomenalism). But overdetermination seems *ad*

hoc, motivated only by a desire to provide some causal role for the mental. If overdetermination is rejected then, given the distinctness of mental and physical events, the only causal role available for the former is as the causes of non-physical, that is, other mental events. But even this seems implausible in view of the fact that at least some mental events can be causally accounted for in terms of prior physical events. Indeed, an empirically well-attested claim of modern science is the *causal completeness of physics*: every event, if it is caused at all, occurs by virtue of physical causes (see Determinism and indeterminism). Consequently, the view that mental events are distinct from physical events plausibly leads to 'mental event epiphenomenalism', or the doctrine that mental events have no physical effects.

Mental event epiphenomenalism is radically at odds with our views about our mental lives. But, fortunately, the line of reasoning that leads to it can be resisted by rejecting the Cartesian view that mental events are distinct from physical events. Descartes' arguments for the distinctness are now generally thought to be weak. His view that mathematical and linguistic behaviour could not be accounted for in terms of antecedent physical events has been undermined by, for example, a computational theory of mind. His more philosophical arguments have not fared much better.

3 Identity theories

This leaves the way open for the position that every mental event *is* a physical event (seeMind, identity theory of). The most prominent contemporary version of this view is the 'token identity theory', due to Donald Davidson (1984). Davidson (§3) holds that every particular (or 'token' mental event is identical to some or other particular physical event, but that *classes* (or 'types') of mental events are not identical to natural classes of physical events (see Type/token distinction). For example, every particular event of someone's *wanting water* may be identical to some or other physical event, but the mental *type* event, *wanting water*, may not be identical to any (naturally definable) physical *type* event (see multiple realizability below).

In many people's minds, however, Davidson's view invites the suggestion that, although mental states and events are identical to physical ones, still mental *properties* are distinct from physical properties (see Property theory). Hence, while the token identity theory avoids mental event epiphenomenalism, it raises the problem of whether, and if so how, mental properties participate in casual relations. Consider a much-discussed example from Dretske (1988): when the soprano's singing causes the glass to break, it is the singing's having a certain *frequency*, not its having a certain *meaning* that is relevant to its having that effect. Given that all causation is physical causation, how could a mental property such as meaning become relevant?

This problem has two parts. One is to characterize the difference between a property's being causally relevant or irrelevant in a causal transaction. The other is to determine when, if ever, mental properties are causally relevant. This problem arises because, on the one hand, folk psychology and cognitive theories seem to assume that mental properties are sometimes causally relevant and, on the other hand, certain philosophical accounts of mental properties raise questions of whether they can be. The view that mental properties are not causally relevant is 'mental *property* epiphenomenalism'. If true, it would entail that, even if mental events are causes of behaviour, their mental properties are not causally relevant to it.

If mental properties were *identical* to the physical properties responsible for behaviour, then there would be no special problem of mental property causation, since it is generally thought that neurophysiological properties are the physical properties causally responsible for behaviour. But there are three reasons frequently cited for thinking that mental properties are not identical to neurophysiological ones: multiple realizability, externalism and subjectivity. The first two apply mainly to intentional mental properties and the third to consciousness.

Multiple realizability. To say that a property is 'multiply realizable' is to say that it can be exemplified in virtue of exemplifying different physical properties. Prime examples of such properties are *functional* properties, or properties an object or state has in virtue of its capacity to exemplify a certain pattern of causal relations. For example, a computer has the property of 'executing a print command' by virtue of running a certain program. Since very different physical objects can exemplify the same causal capacities, functional properties are multiply realizable, a fact reflected in the diversity of physical materials (radio tubes, silicon chips) out of which computers can be made.

It has become the received view in philosophy of mind that certain mental properties are functional properties (see

Functionalism). So, for example, to be a belief is to be a state that is generally caused by inferences from other beliefs and has the capacity to participate in further inferences that cause other beliefs, intentions and so forth. If mental properties are functional properties, then they are not *identical* to neurophysiological properties, though they are realized in us by neurophysiological properties. It may well be that properties other than neurophysiological ones can also realize mental properties. In any case, there seems to be a problem concerning how functional properties can be causally relevant to behaviour. The trouble is that neurophysiological properties are sufficient for causally accounting for behaviour. The functional mental properties they realize seem irrelevant to their capacity to produce behaviour.

Externalism. Externalism is the view that intentional mental properties are constituted, in part, by external relations between thinkers and items external to the thinker. Thought experiments due to Putnam (1975) and Burge (1979) have been taken to support externalism. For example, Putnam imagines two individuals, Oscar and twin-Oscar. They are neurophysiologically identical, but Oscar lives in an environment containing H_2O while twin-Oscar lives on another planet much like earth except that instead of H_2O it has a superficially indistinguishable substance XYZ. According to Putnam and most others who have thought about it, Oscar's expression 'water' refers to H_2O and not XYZ while twin-Oscar's expression 'water' refers to XYZ and not H_2O. The point carries over to their thoughts. Oscar's thought that he expresses by 'Here is some water' is true: he is in the presence of H_2O. It would be false should Oscar travel to twin earth and think the thought in the presence of XYZ (see Content: wide and narrow; Methodological individualism).

If externalism is true then intentional mental properties (like thinking 'Here is some water') are externally individuated since what thought a person has depends on features of their environment. Another way of putting this point is that intentional properties fail to *supervene* on neurophysiological properties (see Supervenience of the mental). This means that two individuals can be identical with respect to their neurophysiological properties while differing in their intentional properties. If neurophysiological properties are causally sufficient for behaviour then it is difficult to see how intentional mental properties can be causally relevant.

Subjectivity. Subjectivity involves the idea that experience is from a point of view. It has been argued that consciousness is essentially subjective and that this subjectivity cannot be accounted for in terms of physical (or any essentially objective) properties of any kind. One line of thought in support of this view is due to Nagel (1974) and Jackson (1986). According to them, it is possible to know all the physical and functional facts concerning the operation of human brains without, for example, knowing what it is like subjectively to experience vertigo. Assuming that knowing what it is like to experience vertigo is itself knowing a fact and that knowledge of a fact is not dependent on how the fact is described (both of which assumptions are questionable), it follows that the property of experiencing vertigo is not a neurophysiological or functional property. At best there are basic nomological connections between objective neurophysiological properties and subjective consciousness (see Colour and qualia; Qualia).

4 Causal relevance

If mental properties are not neurophysiological properties, then how can they be causally responsible for behaviour? One possibility is that they possess *emergent* causal powers. Mental property emergentism means that mental and *not* neural properties are responsible for grounding the causation of behaviour. However, this again violates the causal completeness of physics. So mental property emergentism is not a viable option.

Kim (1993) has argued that the causal completeness of physics *excludes* mental properties from causing behaviour. To suppose otherwise, he claims, is to suppose that behaviour is causally overdetermined by both neurophysiological and mental properties. More generally, Kim claims that the causal completeness of physical properties excludes properties not reducible to fundamental physical properties from possessing causal powers. Kim's conclusion contains both bad and good news for mental causation. On the one hand, it asserts that physical properties, and not mental properties, cause behaviour. On the other hand, mental properties are no worse off than other properties not reducible to fundamental physical properties. In particular they are no worse off, as far as Kim's argument is concerned, than neurophysiological properties since it is likely that these are not reducible to fundamental physical properties either.

A natural response to Kim's argument is to grant that non-reducible macro-properties do not possess causal powers in the way that fundamental physical properties do, but then to attempt to characterize a notion of causal relevance that permits macro-properties to be causally relevant. The motivation for this is the fact that we typically distinguish among an event those macroscopic properties which are, and those which are not, *relevant* to its having certain effects. For example, consider the event of Alma's sneezing and two of its properties - discharging a virus into the air and being loud. The first property but not the second is causally relevant to Bill contracting a cold, and so explains why. The second property but not the first is causally relevant to Hilary saying '*Gesundheit!*', and so explains why. The issue of mental property epiphenomenalism then is the question of whether mental properties are causally relevant to behaviour. If they are not, then it follows that mental properties do not causally explain behaviour; and this has significant consequences for our explanatory practices.

Whether or not mental properties are causally relevant to behaviour depends not only the nature of mental properties, but also on the account of causal relevance. Kim (1993) claims that all higher-level causation including mental causation rides piggy-back on more basic causal relations. He calls such higher-level causation 'supervenient causation' (see Supervenience). However, although higher-level causation may be supervenient causation, the relation is too weak to ground a robust notion of mental causation (Lepore and Loewer 1989). A further condition might be supplied by spelling out causal relevance in terms of counterfactuals (see Counterfactual conditionals). An initial, although not completely satisfactory, proposal (Lepore and Loewer 1987; Horgan 1989) is that an instantiation of *F* is causally relevant to an instantiation of *G* if the counterfactual 'If *F* had not been instantiated then *G* would not have been instantiated' is true. Others appeal to the subsumption of events with their properties under general laws, which may be 'strict' (as in Davidson 1984) or looser, *ceteris paribus* ones (as in Fodor 1989). While deciding among these alternatives will make a difference to the question of mental causation, the question clearly depends upon issues independent of the decision.

Mental illness, concept of

The mad were once thought to be wicked or possessed, whereas now they are generally thought to be sick, or mentally ill. Usually, this is regarded as a benign decision by a more enlightened age, but some see it as a double-edged sword - one that simultaneously relieved and robbed the mad of responsibility for their actions, eventually delivering more compassionate treatment, but also disguising value-laden judgments as objective science. The issue is made more difficult by the diversity of conditions classified as psychiatric disorders, and by the extent to which their causes are still ill understood. But the difficulty is also conceptual: what, after all, is physical illness? People usually agree that it involves abnormal body functioning, but how do we decide what is normal functioning? And even supposing that we know what we mean by a sick body, is there a parallel notion of a sick mind that is more than metaphor?

1 Physical illness and normal functioning

Somatic medicine is both applied biology and a social institution charged with curing and caring for people with complaints that have physiological causes. The ill-health concepts - illness, disease, injury, disability, and so on - reflect this dual nature.

On the one hand, it seems that some degree of biological functional impairment is a necessary condition for ill-health of any kind. That is why childbirth, teething and large noses can cause distress without counting as ill-health, for although they have physiological causes, they do not *per se* involve malfunctioning. On the other hand, the various ill-health concepts introduce additional social, ethical, or clinical considerations. For instance, injuries generally result from a visible collision with the environment, while diseases tend to be heritable or infectious and have less visible causes (for example, micro-organisms, viruses, genes). Furthermore, an illness is something a person has (your little finger can be injured or diseased, but not ill), and illness qualifies you for the sick role, which involves being excused from many normal duties and deserving of special care.

Due to the plethora of ill-health concepts, philosophers often use illness as a term of art - a catch-all that includes all states of ill-health. Neither in this sense, nor in its ordinary sense, is it controversial that it is, in part, a value-laden concept, or that it involves a core of biological dysfunction. The main controversy concerns the notion of dysfunction: is it also value-laden, or can a completely descriptive account of it be given?

Talk about biological functions is clearly normative in some sense. We ask of our bodily parts. Is it functioning properly? What is it supposed to do? Is it malfunctioning? But what is the basis of such norms?

Robert Cummins (1975) argues that functions have their most important explanatory role in biology in functional analysis - a recursive conceptual decomposition of a system and its activities into simpler and simpler subsystems and simpler and simpler tasks. Functions are causal contributions to some activity of a system that is explained by such an analysis, he says. The contribution a part makes is an objective feature of the system so described, but the activity we choose to explain depends on our interests, he adds: in physiology, we are interested in survival and reproduction and contributions to these (see Functional explanation).

Functional analysis is certainly important to biology, but many think that Cummins has not captured its normative dimension. There are numerous problems. For instance, we are most interested in how people die of cancer, but a tumour’s causal contribution to death, although often complexly achieved and a candidate for a Cummins-style analysis, is not an instance of proper functioning.

Normativists claim that normal functioning is further value-laden: while we are deeply interested in both life and death, ease and pain, fertility and infertility, capacity and incapacity, we value the first of each pair, not the second, and that is why contributions to the one, and not the other, are cases of proper functioning, they say. In support, they emphasize the cultural relativity of disease classifications. (Engelhardt’s history of masturbation in Western medicine is a good example, see Engelhardt and McCartney 1981). But this evidence is also compatible with the claim that doctors can make mistakes. If there are descriptive biological norms, it does not follow that doctors will never be biased, confused or even ignorant, when trying to apply them.

Naturalists claim that there is a purely descriptive notion of normal functioning. Christopher Boorse (1976) offered

a theory somewhat like Cummins's, but the goals of survival and reproduction were, he argued, biologically given. As natural selection continually modifies a species-design in favour of an individual's survival and reproduction, these are the goals towards which organisms are goal-directed, he says. To abstract away from idiosyncratic deviations, Boorse suggested that the function of a trait is, roughly, its species-typical contribution to the individual's survival and reproduction, but *prima facie* this seems problematic, for deviations from proper functioning can be typical (for example, in epidemics or pandemics).

Aetiological theories (following Wright 1973) have become popular. According to these, the proper function of a trait is what it was selected for. On this kind of account, it is the function of the kangaroo's pouch to protect her young because that is what the pouches of ancestral kangaroos did that caused the underlying genotype to be selected.

Some are dissatisfied with both of these naturalist theories (see Bigelow and Pargetter 1987, but also Neander 1991) and offer still further suggestions for how biological norms should be understood.

A general feature of naturalist accounts is the claim that systems that have proper functions are the outcome of, or are subject to, selection. For biological functions, the relevant selection process is natural selection: a blind, impersonal and decidedly amoral force. If so, biological norms are not determined by what we value, nor by what God values, but rather by what matters for natural selection. There is no implication, therefore, that what is normal or natural is to that extent desirable. Our values need not be those of natural selection (hence contraception). Indeed, there is no deducing 'ought' from 'is' here, on either type of account. According to the normativist, judgments about normal functioning are value-laden anyway, and so judgments concerning them are as contentious as value-laden judgments generally are.

2 Mental illness

There is no doubt that mental illness can involve great distress and incapacity, or that it can be life-threatening. But does it involve dysfunction in the sense we have been discussing?

A partial answer is easy. Some psychiatric disorders are uncontroversially brain diseases that belong to medicine proper, for they clearly involve straightforward physiological dysfunction - the neurones having atrophied (as in Alzheimer's Disease) or some such thing. The controversial cases are those where, if there is any dysfunction characteristic of the purported disorder, it can only be described in psychological, not physiological, terms (that is, in terms of the conscious or unconscious beliefs and desires of the person). For instance, if a human being desires sex with a five-year-old child, we describe that desire as sick. But is this description merely metaphorical, or is there a genuinely medical judgment to be made here, as well as a moral one? (The causes of mental illness are often complex and multifarious, and there are many mixed cases between the two extremes just mentioned - the organic syndromes and the purely psychological disorders.)

Whether there can be specifically psychological dysfunction will depend partly on the nature of mind and partly on the nature of functions. For instance, if the best theory of functions gives a central place to functional analysis and to what a thing is selected for, it will depend on whether the mind lends itself to a functional analysis of the appropriate kind, and on whether (or to what extent) the mind is subject to selection.

Even if there is specifically psychological dysfunction, (somatic) medicine might still be irrelevant to its treatment, and so psychiatry might still need to be de-medicalized, as some people argue. These days, the mental illness debate is generally based on the assumption that the mind is the brain, and that mental processes are brain processes (see Mind, identity theory of). But there is still much controversy regarding how talk of the one relates to talk of the other. Boorse (1987), for example, argues that psychology and biology are autonomous disciplines. Expertise in somatic medicine is therefore irrelevant to the treatment of psychological dysfunction, he argues, and there is no call for psychiatrists to have (somatic) medical training (although the latter is needed in a supporting role, for example, to first rule out the possibility of physiological causes.)

Others see psychology and biology as more intimately integrated. One popular, but highly controversial, approach to describing the mind is to try to characterize mental states and processes using a biological notion of a proper function (see Semantics, teleological). Many also believe that much of our psychology (learning processes, concepts and so on) is innate and part of our biological endowment (see Nativism), and hence presumably, but not

inevitably, the result of natural selection.

These strands in contemporary philosophy of mind are the ones that promise to provide the most literal interpretation of mental illness, but until we have a more complete understanding of the theoretical details, as well as of the working of the mind, the implications for particular conditions currently classified as psychiatric disorders may well remain obscure.

3 Related ethical issues

Resistance to classifying mental problems as medical problems often centres around concern for the autonomy of, and respect for, persons.

Except in so far as we blame someone for becoming ill, we do not as a rule blame them for the symptoms of their illness (for example, we might blame someone for smoking and so for developing emphysema, but we do not otherwise blame them for coughing). This seems to imply that we are not held responsible for symptoms, and mental illness is often thought to excuse a person from responsibility. The other side of this double-edged sword is that the agency of those labelled mentally ill is assumed to be diminished, and their rights as persons (for example, to choose for themselves what is in their own best interest) may consequently be denied.

There are a number of reasons why the picture just described is too simple, however. For one thing, symptoms are not usually actions. But our behaviour could be an action that is caused by beliefs and desires, and it could also be a symptom, because the beliefs and desires themselves are caused in an abnormal way - they might be caused by depression due to hormonal imbalance, for example. It is unclear why those who act from beliefs and desires that are symptoms of either somatic or mental illness should be excused just because of this fact. If a paedophile’s desire to have sex with children is no more compelling than the embezzler’s desire for money, or the jealous husband’s desire for revenge, paedophiles are equally responsible for their actions, some argue (see Feinberg 1981). On this view, mental illness provides no special ground for excuse. It excuses only if it causes the agent to be blamelessly ignorant or to suffer irresistible compulsion, which are sufficient excuses in their own right.

Similar care has to be taken with the difficult issue of the competence (and civil rights) of the mentally ill. Much mental illness is localized or episodic, and will often be irrelevant to the person’s capacity to make reasonable decisions about, for example, voting in an election, deciding on treatment, or selling the family home. Hard issues arise, however, when a mentally ill person is judged to be generally incompetent. Should we give them similar rights to those we give to children, even if their condition is believed to be irreversible, for example?

Mental states, adverbial theory of

According to the adverbial theory, there are no mental objects of experience, no pains, itches, tickles, after-images, appearances. People certainly feel pains and have after-images; external objects certainly present appearances to people viewing them. But pains, after-images, and appearances are not real things. Statements which purport to be about such mental objects have a misleading grammatical form. In reality, such statements are about the ways in which people experience or sense or feel.

1 Motivation

Suppose you are having a tooth drilled. Suddenly you feel intense pain. This is an objective fact about you, not dependent for its existence on anyone else seeing or thinking about your situation. But the pain you are feeling - that particular pain - is private to you. It is yours alone, and necessarily so. No one else could have that particular pain. Of course, conceivably somebody else could have a pain which felt just like your pain, but only you could have that very pain. What is true for this one pain is true for all mental objects of experience, for example after-images, appearances, itches, tickles. None of these items of experience can be shared. I can’t have your images or feel your tickles. Physical objects, however, are not necessarily private in this way. Any physical object that is mine could be yours, my watch, for example, or even my heart (see Privacy).

There is another striking fact about mental objects of experience, or phenomenal objects, as they are often called. Any pain or itch or image is always *somebody’s* pain or itch or image. Likewise, any appearance is always an appearance *to* someone or other. Each mental object of experience necessarily has *an* owner, unlike ordinary physical objects, for example, trees or tables or even legs. Legs can exist amputated, and trees and tables can belong to no one at all.

Any philosopher who wants to view the mind, and its contents, as natural physical phenomena faces a problem with respect to the necessary privacy and necessary ownership of phenomenal objects. The adverbial theorist solves this problem by arguing that while it is certainly true that people feel pains and itches, and have images, this way of talking is misleading. Really there are no such things as pains, itches, and images. The world itself contains no phenomenal objects. So, there is, in reality, nothing to have the physically problematic properties.

2 Elaboration

How can it be true that people feel pains, even though there really are no pains for them to feel? The answer, according to the adverbial theorist, is that our ordinary way of expressing ourselves here is deceptive. Grammatical form is sometimes misleading. Just as it can be true that the average family has 1.2 children even though there really are no families with a fraction of a child, so too you can feel an intense pain even though there really are no pains.

But what is it that we are asserting, then, when we say, in ordinary parlance, that someone *has* a blue after-image or a throbbing pain or a terrible itch? In the case of the claim that the average family has 1.2 children, the answer is reasonably obvious. We are talking about numbers, and what we are really asserting is that the number of children divided by the number of families equals the number ‘1.2’. In the case of phenomenal talk, however, if its grammatical form is indeed misleading, the answer is much less obvious. It is to be found, according to the adverbial theorist in our ordinary talk of other things - of smiles and limps, of voices and stutters.

Suppose we ask ourselves whether there really are, in the world, any such things as limps. If we reply ‘Yes’, then we seem to face some puzzling questions just like the ones raised for phenomenal objects. If Patrick has a pronounced limp, then can Paul have that very same limp (the token limp Patrick has, not one just like it but numerically different)? Can Patrick’s limp exist without anyone at all having it?

One reasonable response to these puzzling questions is to deny that there really are such things as limps, to which people are related by the ’having’ relation. On this view, when we say that Patrick has a pronounced limp, what we are really saying is that Patrick *limps* in a pronounced manner. Likewise for smiles, voices, and stutters. If Patrick also has a charming smile, a loud voice, and a noticeable stutter, what is really the case is that he smiles charmingly, speaks loudly, and stutters noticeably. There are no smiles, voices, and stutters, conceived of as things

people have.

Analogously, according to the adverbial theorist, there are no pains, itches, or visual images, conceived of as objects people have. Instead, to have a terrible itch is just to itch terribly; to have a throbbing pain is to hurt throbbingly or in a throbbing manner. Finally, to have a blue after-image is just to sense in a certain way, a way we may dub ‘bluely’. Now the problem for physicalism supposedly disappears. There are no phenomenal *objects* as such, and so there is no question of trying to accommodate their necessary privacy and ownership in the physical world.

Unfortunately, life is not that easy. To begin with, talk of people sensing bluely or hurting throbbingly is hardly everyday. It cries out for further explanation. Secondly, if there are no phenomenal objects, then just what is it that makes phenomenal talk true? If, when I have a terrible itch, it is really true that I itch terribly, then what exactly is it about me which *makes* this true? Some account is needed here in order to show that the possession by me of a terrible itch has really been repudiated and not just hidden under a verbal smokescreen.

At this point, the adverbial theory of sensation or experience, splits into two. To understand these alternatives and their respective costs and benefits, it is necessary to make some brief general remarks about adverbs.

There are two major theories of adverbs in the philosophical literature: the predicate operator theory and the event predicate theory (see Adverbs). According to the latter view, adverbs, or at least a very wide range of adverbs, are best understood as adjectives that are true of events. Consider, for example,

(1) Patrick is stuttering noticeably.

If we are to bring out what it is that makes (1) true, we should restate it, on the event predicate theory, as

(1a) There is an event of stuttering, which has Patrick as its subject, and that event is noticeable.

Similarly,

(2) Patrick is speaking loudly.

should be recast as

(2a) There is an event of speaking, which has Patrick as its subject, and that event is loud.

So, the adverbs ’noticeably’ and ’loudly’ are really functioning as adjectives or predicates that apply to events, in the one case, to a stuttering, and in the other, to a speaking. What must exist, then, for Patrick to stutter noticeably or speak loudly is a noticeable stuttering or a loud speaking, of which Patrick is the subject.

This view has a number of virtues, not the least of which is that it requires no alteration, or addition, to the materials available in first order quantificational logic, as far as the formal evaluation of arguments in which sentences like (1) and (2) occur (see Predicate calculus). Secondly and relatedly, it provides us with a very simple explanation of why (1), for example, entails

(3) Patrick is stuttering.

(3) is reconstructed as:

(3a) There is an event of stuttering, of which Patrick is the subject.

and (3a) follows from (1) via elementary logical rules.

The alternative view takes adverbs to be operators which turn the predicates they modify into more complicated predicates. In (1), for example, ’noticeably’ is held to operate on the predicate preceding it, namely ’stutters’, and to convert that predicate into a syntactically more complicated predicate, namely ’stutters noticeably’. The idea is that adverbs stand for functions which map the properties expressed by the properties they modify onto other properties. On this view, what makes (1) true is not the fact that Patrick is the subject of an event (a noticeable stuttering) nor the fact that Patrick owns a special object (a noticeable stutter) but simply the fact that Patrick has a certain property, that of stuttering noticeably. So (1) really is a subject-predicate sentence, just as it appears to be.

There is no hidden existential quantification, as there is the event predicate theory proposal.

This approach requires the admission that the resources of standard logic do not suffice to come to grips with arguments containing adverbs, together with an account of operator detachment which will validate inferences like the one from (1) to (3) above. So, it has significant costs. On the other hand, it allows us to take sentences like (1) and (2) entirely at face value. These sentences certainly look to be of the straightforward subject-predicate variety, and, by golly, so they are on the predicate operator proposal.

On the event version of the adverbial theory of sensation, statements putatively about phenomenal objects like pains and itches are really about events like hurtings and itchings. By contrast, on the predicate operator version of the adverbial theory, statements putatively about phenomenal objects are really about people or other sentient creatures and the phenomenal properties they instantiate, properties like itching terribly or hurting throbbingly.

3 Objections

These two developments of the adverbial theory face some serious difficulties. To begin with, the predicate operator theory is hard pressed to account for the truth of ordinary statements putatively about multiple phenomenal objects. For example, suppose that after staring at a bright light and turning away, I report the following:

(4) I have four pink after-images.

It is not a straightforward matter to provide a plausible account of what in the world makes this true, given only phenomenal properties that I possess. The problem becomes especially difficult once it is appreciated that glibly proposing

(4a) I sense four-pink-ly,

or some such contrived statement as the analysis, apparently fails to account for the fact that (4) entails, for example,

(5) I have at least three after-images.

It certainly *looks* here as if, given this entailment, (4) is true if, and only if, there are four pink after-images that I have. Another related difficulty arises in connection with the following two statements

(6) I have both a red, square after-image and a blue, round after-image.

and

(7) I have both a blue, square after-image and a red, round after-image.

These statements evidently are not equivalent: one can be true without the other. But if we analyse the former by

(6a) I sense redly and squarely and bluely and roundly.

and the latter by

(7a) I sense bluely and squarely and redly and roundly.

then the difference between (6) and (7) is lost. For the order of the conjuncts in a conjunction makes no difference to the conditions under which it is true.

These problems, it should be noted, are also challenging for the event version of the adverbial theory. In this case, however, there is a reasonably straightforward reply. Allow there to be as many different sensings as there *appear* to be after-images referred to in the original statements. Then (4) becomes

(4b) There are four pink sensings of which I am the subject.

Now the entailment to (5) is easy to explain. Likewise, there is no difficulty in distinguishing (6) and (7). In both cases, there are two sensings, but they have different properties.

But does it really make sense to talk of my undergoing four simultaneous sensings, each with the same property? Some philosophers have certainly thought not. And it must be admitted that it is not at all easy to find clearcut examples from ordinary life of cases where a single individual is the subject of multiple simultaneous events of exactly the same sort (and not involving any other objects). I can listen to you with my left ear and also simultaneously listen to you with my right, or I can inhale deeply through my left nostril and at the same time inhale deeply through my right, but in both of these cases other objects are also involved (namely ears and nostrils). I can simultaneously be the subject of a singing and a walking and a smiling, say, but apparently I cannot simultaneously be the subject of three singings or three walkings or three smilings.

So, the event version of the adverbial theory faces a serious challenge here, too. And there are other problems. What, for example, can it possibly mean to call an event ’pink’ or ‘square’?

The difficulties I have raised here have been addressed by adverbial theorists. And I think it is fair to say that there is no knockdown objection to the view. But whether it really provides us with the best response to the problems posed by the necessary privacy and ownership of phenomenal objects is a matter of considerable dispute.

Finally, although the adverbial theory is usually associated with sensory experience, it is occasionally generalized so as to apply to all mental states. Under this generalization, there are no beliefs or desires or fears that people *have*, any more than there are after-images or itches or pains. As before, there are again two possible ways of developing this proposal further, one of which countenances believings, desirings, and fearings, and the other of which restricts itself to the attribution of the appropriate psychological properties.

Mereology

Mereology is the theory of the part-whole relation and of derived operations such as the mereological sum. (The sum of several things is the smallest thing of which they are all parts.) It was introduced by Leśniewski to avoid Russell's paradox.

Unlike the set-membership relation, the part-whole relation is transitive. This makes mereology much weaker than set theory, but gives the advantage of ontological parsimony. For example, mereology does not posit the proliferation of entities found in set theory, such as $\emptyset, \{\emptyset\}, \{\{\emptyset\}\}, \ldots$.

Mereology has occasioned controversy: over whether many things really have a mereological sum if they are either scattered or, even worse, of different categories; over the uniqueness of sums; and over Lewis' claim that the non-empty subsets of a set are literally parts of it.

1 Classical mereology

Mereology is the theory of the part-whole relation. It was introduced by Leśniewski (1916) to avoid Russell's paradox (see Paradoxes of set and property). Taking the part-whole relation as primitive, we define a proper part as a part which is not identical to the whole. We define disjointness to mean having no part in common. Then, in addition to the transitivity of the part-whole relation, the following axiom schema, unique composition, characterizes classical mereology.

If there is some *F*, there is precisely one thing (the sum or fusion of the *F*s) of which every *F* is a part and which has no part disjoint from every *F*.

The supplementation principle now follows, namely that if *a* is a proper part of *b*, then *b* has some proper part disjoint from *a*. For otherwise both *a* and *b* are sums of all the parts of *a*, contradicting uniqueness. It also follows that there is a sum of everything, *U*; that any thing *a* which is not *U* has a complement, namely the sum of everything disjoint from *a*; and that any two overlapping things *a* and *b* have a product (or intersection), namely the sum of all things which are parts of both *a* and *b*. Apart from the absence of a null individual, mereology has, with these operations, the structure of a Boolean algebra (see Boolean algebra §1).

Strictly speaking, what we take as the characteristic axiom schema will depend on the logic mereology is an extension of. In the above this is the predicate calculus with identity. Leonard and Goodman's formulation (the calculus of individuals) is an extension of (a fragment of) set theory. In that case, unique composition is the axiom that any non-empty set of individuals has a sum. Or suppose, like Lewis (1991), you are extending a logic which permits plural quantification. Then unique composition could be formulated as:

For any things there is one thing which has those things as parts and which has no part disjoint from those things.

Yet again, in a finitist mereology the formulation would be:

For any *a* and *b* there is a unique *c* of which *a* and *b* are parts and which has no part disjoint from *a* and *b*.

Classical mereology is, therefore, a family of theories, with unique composition adapted to the context.

Both the transitivity of the part-whole relation and unique composition have been rejected as counter-intuitive. Cruse (1979) gives an example, later discussed by Simons (1987: 107), which illustrates the supposedly counter-intuitive character of the transitivity of the part-whole relation: a handle is part of a door, a door is part of a house but, it might seem, the handle is not part of the house. This objection is based on a controversial interpretation of 'part' to mean 'significant part'.

Unique composition may be conveniently divided into the existence of sums and the uniqueness of these sums. Let us first consider uniqueness. The problem, as stated by Simons (1987:115-17), has to do with 'continuants', namely things which endure without having temporal parts. Continuants are themselves controversial, but let us suppose that cats are continuants. Now consider a whole cat, Tibbles, her tail, and the remainder of Tibbles, called Tib. If Tibbles loses her tail then, Simons argues, Tibbles and Tib will be non-identical things with precisely the

same parts. They are non-identical because they are identical, respectively, to Tibbles and Tib prior to tail loss, which are obviously non-identical (in other words, Tibbles is still Tibbles with or without her tail). A similar problem can be stated in modal rather than temporal terms. While there may be several solutions, we might well restrict classical mereology to categories of items which are not continuants. In that case Simons' nonclassical mereology would be appropriate for continuants.

The existence of sums of disparate collections has seemed too strong to many. Here it is important to note that mereology is demonstrably consistent, so there is no analogue of Russell's paradox. The objection, therefore, is not formal. The worst case is the existence of sums of items from different categories, such as: a kettle, the process in the kettle in which water boils, the spatiotemporal region in which the process occurs, the property of being at $100^{\circ}\mathrm{C}$, and the relation of contiguity. Even though all those items might be thought of in connection with the activity of boiling water, it seems queer to say there is something which is the sum of them.

Lewis has defended the existence of disparate sums on the grounds that describing the sum is doing nothing more than describing the parts, for there is no extra ingredient which somehow unifies the parts into a whole (1991: 79-81). He also points out that attempts to avoid the sum of a scattered collection of items of the same category will fail because in such cases queerness is a matter of degree. This leaves open, however, the possibility of restricting unique composition to sums of items all taken from the same category.

2 Mereology, set theory and atoms

An atom may be defined as something which has no *proper* part. We may ask whether there are any atoms and whether every thing is a sum of atoms. If the answer to the first question is negative then a mereology is called 'atomless'; if the answer to the second is positive then it is 'atomistic'. Now mereology does not have to be either atomistic or atomless - it might, for instance, be the case that every object has proper parts even though the space they occupy is a sum of points. It seems rather less plausible that any one category of thing (for example, physical objects) should have both atoms and atomless parts. Mereology restricted to a single category would seem, therefore, to be either atomistic or atomless. For example, mereology restricted to spatiotemporal regions is atomistic if all regions are sums of points, but atomless if points are idealized limiting cases of arbitrarily small regions (see Whitehead 1919; Whitehead §2; see also Mortensen and Nerlich 1978; Clarke 1985).

Mereology is of theoretical interest partly because it has been used to provide either a replacement for, or a formulation of, the theory of sets. Because a sum of atoms has a unique decomposition into atoms, sums behave like sets of atoms. The chief difference between mereology and set theory is that two different sets of non-atoms, say, $\{a+b, c+d\}$ and $\{a+c, b+d\}$, can have the same sum, $a+b+c+d$. It was hoped that the resources of mereology would none the less be enough to replace sets in the foundations of mathematics. Thus Goodman and Quine (Goodman 1972: 173-98) showed how the ancestral (that is, a chain of instances) of a relation could be defined using the part-whole relation, avoiding set theory. They also showed how various statements such as 'There are exactly one-third as many Canadians as Mexicans' can be handled using mereology. Their approach ran into difficulties, however, with quantified numerical formulas, such as 'For all *n*, $n+n=2n$'.

Lewis, in his version of nominalistic set theory, adopted a rather different strategy, namely to imitate set theory using the resources of mereology (see Lewis 1991: 21-8). The chief difficulty seems to have been that without the resources of set theory the materials are lacking with which to construct enough pseudo-sets. Thus a sound Ockhamist reason for preferring mereology to set theory - its inability to generate infinitely many things out of just one thing - restricts its use as a substitute.

Rather different is Lewis' later programme of treating the theory of sets and proper classes as itself an extension of mereology (1991). Excepting the special case of the empty set, we may treat subclasses as parts and thus treat set theory as the extension of mereology obtained by adjoining the singleton operator. This operator forms unit sets, which are always atoms, out of individuals. Lewis is in favour of treating it as primitive, but, relying on results by Burgess and Hazen, he also shows how we can develop an alternative, structuralist account, according to which there are many possible singleton operators, between which set theory does not choose.

Merleau-Ponty, Maurice (1908-61)

Merleau-Ponty belongs to the group of French philosophers who transformed French philosophy in the early post-war period by introducing the phenomenological methods of the German philosophers Husserl and Heidegger. His central concern was with 'the phenomenology of perception' (the title of his major book), and his originality lay in his account of the role of the bodily sense-organs in perception, which led him to develop a phenomenological treatment of the sub-personal perceptions that play a central role in bodily movements. This account of the sub-personal aspects of life enabled him to launch a famous critique of Sartre's conception of freedom, which he regarded as an illusion engendered by excessive attention to consciousness. None the less, he and Sartre cooperated for many years in French political affairs, until Merleau-Ponty became exasperated by the orthodox Marxism-Leninism of the French Communist Party in a way in which Sartre, who remained a fellow-traveller, did not. As well as several substantial political essays, Merleau-Ponty wrote widely on art, anthropology and, especially, language. He died leaving some important work incomplete.

Although his work is still esteemed within the French academic establishment, his influence in France has waned, because of a tendency there to study his German forebears almost to the exclusion of all else. But elsewhere, and most notably in the USA, Merleau-Ponty's work is widely studied, especially now that questions about the distinction between personal and sub-personal aspects of life have become so prominent.

1 Life

Merleau-Ponty studied philosophy at the École Normale Supérieure, graduating in 1930. As a student he was quickly drawn towards the works of the German phenomenologists, having attended Husserl's 1929 lectures in Paris (the 'Cartesian Meditations') and studied Heidegger's writings (see Husserl, E.; Heidegger, M.). He wrote his first book, *The Structure of Behavior*, before serving briefly in the French Army in 1939-40. During the German Occupation he taught at the Lycée Carnot in Paris and wrote his major work, *The Phenomenology of Perception*, which was published in 1945. In the same year he took a position at the University of Lyon, before returning to Paris in 1950 as Professor of Psychology at the Sorbonne; in 1952 he moved to the prestigious Chair of Philosophy at the Collège de France, a position which he held until his early and unexpected death in 1961.

2 Mind and body

Much of Merleau-Ponty's first work, *The Structure of Behavior* (1942) is devoted to a detailed critical discussion of physiological psychology and the attempt to provide on its basis a reductive explanation of behaviour. In developing his argument Merleau-Ponty draws on Gestalt psychology and especially K. Goldstein's *The Organism* which emphasizes the holistic features of the life of organisms. Merleau-Ponty takes over Goldstein's holism and incorporates it into what he terms a 'dialectical' conception of the structures of behaviour, according to which as organisms evolve and become more sophisticated, higher 'forms' of behaviour develop which transform the life of the organism. So the new capacities characteristic of these higher forms are not simple additions to an otherwise unaltered neurophysiology; instead, through a process of 'dialectical' assimilation, these new capacities bring with them changes in the functioning of the underlying neurophysiology (see Gestalt psychology).

Merleau-Ponty argues that this dialectical approach enables him to reject reductive theories without invoking the kind of vitalism espoused by Bergson (see Vitalism). Equally, he argues, it provides a way of accommodating the phenomena of consciousness without dualist metaphysics: for, he writes, 'man is not a rational animal. The appearance of reason and mind does not leave intact a sphere of self-enclosed instincts in man' ([1942] 1963: 181). Thus there can be no partition of 'mind' from 'body' in human life: the mental is intrinsically bodily, a theme Merleau-Ponty illustrates through the role of the sense-organs in perception. Equally the body is intrinsically mental, in the sense that there can be no adequate understanding of human behaviour that does not conceptualize it as the behaviour of a normally rational agent. Merleau-Ponty's comment on Watson's behaviourism shows his aspirations clearly:

> what is healthy and profound in this intuition of behavior found itself compromised by an impoverished philosophy…. When Watson spoke of behavior he had in mind what others have called *existence*; but the new notion could receive its philosophical status only if causal or mechanical thinking were abandoned for

dialectical thinking.

(Merleau-Ponty [1942] 1963: 226)

3 *The Phenomenology of Perception*

Merleau-Ponty ends *The Structure of Behavior* with some enigmatic remarks to the effect that, just as there is no satisfactory causal account of perception, a realist account of the perceived world is equally unsatisfactory. With these remarks Merleau-Ponty points towards a main theme of his most important work, *The Phenomenology of Perception* (1945). An important difference, however, between the two books is that, as its title and preface (‘What is Phenomenology?’) indicates, the approach adopted in the second book is explicitly ‘phenomenological’. The central theme of Merleau-Ponty’s phenomenology is that a full understanding of the natural and social worlds which we inhabit inevitably leads back to aspects of our experience through which, in some sense, meaning is bestowed upon the objects of experience. Thus he sees the primary task of philosophy as one of quasi-Platonic *anamnesis* (see Plato §§10-11), of re-awakening within us a recognition of these meaning-bestowing aspects of our own experience so that we can grasp how we are integrated into these worlds and how they, in their turn, are dependent upon us: philosophical reflection, he writes, ‘steps back to watch the forms of transcendence fly up like sparks from a fire; it slackens the intentional threads which attach us to the world and thus brings them to our notice’ ([1945] 1962: xiii). In developing this phenomenology Merleau-Ponty often expresses his debts to Husserl’s late works, especially the unpublished papers which he had studied at Louvain. But how far, in fact, Merleau-Ponty is developing themes from Husserl’s writings is disputable. He himself indicates his rejection of the transcendental subjectivism that is a prominent theme of most of Husserl’s writings; similarly when he proclaims the impossibility of completing the phenomenological reduction and affirms the inseparability of essence and existence he is implying that Husserl’s project of essentialist phenomenological analysis can never be accomplished. Thus it is arguable that Merleau-Ponty’s conception of phenomenology is in fact closer to that characteristic of Heidegger’s *Being and Time*, and one can certainly use Merleau-Ponty’s detailed accounts of experience as a way of filling out Heidegger’s all-too-abstract characterization of human life.

Merleau-Ponty’s concentration upon perception rests on a thesis which is fundamental to his phenomenology, namely that perception is ‘transcendental’ in the sense that it cannot be adequately understood from within a fully objective, scientific conception of human life. In part this thesis just draws on the argument of *The Structure of Behavior*; but at a deeper level Merleau-Ponty argues that because perceptual experience is epistemologically fundamental it cannot be the case that perception itself is fully comprehended within the explanatory perspective of natural science, since this employs a conception of the world which draws on features that owe their significance to perceptual experience itself. Merleau-Ponty likes to adapt a phrase from the poet Paul Valéry to express this feature of perception: it is, he says, ‘the flaw in this great diamond’ since ‘we can never fill up, in the picture of the world, that gap which we ourselves are’ ([1945] 1962: 207). Merleau-Ponty’s argument is, therefore, that the realist naturalizing project faces an inescapable blind-spot in connection with perception. Whether Merleau-Ponty is right about this remains disputable - his critics will maintain that, once we separate epistemological from metaphysical priorities, we can see that it is legitimate to regard our own experiences as facts caught up within, and dependent upon, the causal order of the natural world, even if we also acknowledge that our beliefs concerning this causal order rest upon perception.

This is the kind of issue which realists and idealists can debate endlessly, but whatever the outcome of that debate there can also be agreement that Merleau-Ponty’s line of thought leads into one of the most innovative programmes of twentieth-century idealism. Central to this is his discussion of the status of the body. Merleau-Ponty once again uses Goldstein’s work - in this case his studies of a patient (Schneider) who had suffered brain injuries during the First World War. But what is new in *The Phenomenology of Perception* is the use that Merleau-Ponty makes of his phenomenology in the characterization of Schneider’s case and then, by an inversion, his use of Schneider’s case to revise the phenomenological approach itself. Schneider’s injuries, he argues, have brought with them the loss of the sub-personal perceptual fields, bodily spaces and tacit anticipations of possibilities that underpin ordinary human agency. So Schneider’s disability is not merely neurophysiological; nor is it just a disorder of a consciousness detached from behaviour; instead it bears witness to the normal sub-personal union of mind and body through which a form of intentionality is expressed in unreflective but organized bodily movement. Once the further step is taken of recognizing that this is the basic form of

intentionality, it follows that the phenomenological perspective itself needs to be relocated from the personal sphere of explicit thought to the sub-personal domain of bodily movement; thus, as Merleau-Ponty puts it, Schneider's case 'forces us to acknowledge an imposition of meaning which is not the work of a universal constituting consciousness' ([1945] 1962: 147) (see Intentionality).

Merleau-Ponty characterizes this revised phenomenological perspective as one in which the body is conceived as 'a natural self and, as it were, the subject of perception' ([1945] 1962: 206). Because of his transcendentalism concerning perception, the body thus conceived is not the body as characterized within the objective perspective of the natural sciences: 'what prevents it ever being an object…is that it is that by which there are objects' ([1945] 1962: 92). His term for the body thus conceived is 'the phenomenal body' ([1945] 1962: 106) and he argues that by following the intentional threads which link the phenomenal body to the world we will be led to recognize the inadequacy of a purely objective conception of the world as a totality of objects, and to replace it with that of the 'phenomenal field', conceived as 'the horizon latent in all our experience and itself ever-present and anterior to every determining thought' ([1945] 1962: 92).

At this point the similarity with Kantian themes concerning space will be obvious (see Kant, I. §5), and Merleau-Ponty provides an extended account of the a priori status of the practical horizon which, he holds, enters into all our perceptual fields. But what is distinctive about Merleau-Ponty's account is its integration into a phenomenological psychology which preserves the basic metaphysics of transcendental idealism by making the body the transcendental subject. Arguably, however, in *The Phenomenology of Perception* Merleau-Ponty still replicates Husserl's problematic transcendental/empirical division of the self with his distinction between the 'phenomenal' and the 'objective' body. Hence it is notable that when he returns to the topic in his final work, *The Visible and the Invisible*, he attempts to go beyond this distinction by arguing that there is a yet more fundamental conception of the body - as 'flesh', which is a conception of the body that admits both an objective specification as 'a thing among things' and a phenomenal specification as 'what sees and touches' ([1964] 1968: 137). Indeed, despite the title of the book, it is significant that Merleau-Ponty here treats the sense of touch as phenomenologically fundamental and even, implausibly, construes sight as a species of touch (as 'a palpation with the look' ([1964] 1968: 134)); for touch has often been regarded as the sense which by manifesting the independent resistance of things reveals most clearly their objectivity. But because the book is incomplete it is not clear just how far this rebalancing of emphasis, to give equal weight to the 'objective' and the 'phenomenal' sides of life which are 'intertwined' in the human body, implies the need for a reworking of his whole phenomenology in a more objectivist direction. But it is clear, I think, that the position remains recognisably idealist in spirit, partly indeed through his explicit affirmation of the ideality of 'the flesh' ([1964] 1968: 152).

4 Consciousness and freedom

In the final chapters of *The Phenomenology of Perception* Merleau-Ponty uses his account of the sub-personal elements of life to elucidate the characteristic marks of personal life - self-consciousness and freedom. His discussion of these themes is, in part, an argument against their treatment by Sartre in *Being and Nothingness*, which was published two years earlier in 1943. Central to Sartre's account was the thesis that consciousness has a distinctive 'being' as 'being-for-itself' - that is, self-conscious - which is supposed to yield the conclusion that consciousness manifests an inescapable and absolute freedom (see Sartre, J.-P. §3). As against Sartre, therefore, Merleau-Ponty argues that both self-consciousness and freedom are achievements that cannot be understood in isolation from the sub-personal aspects of life from which they are absent. They do not constitute an inescapable fate to which we are condemned; instead they are just the high points in the ebb and flow of our existence.

In the case of consciousness Merleau-Ponty argues that it is because 'all consciousness is, in some measure, perceptual' ([1945] 1962: 395), in the sense that it draws upon our habitual sub-personal experience of the world, that self-consciousness is both capable of genuinely extending our knowledge and also vulnerable to error and illusion. A form of self-consciousness that was not thus vulnerable would be so totally detached from this tacit background that it would lack the concepts with which this background furnishes us and could, therefore, tell us nothing about ourselves. Similarly the exercise of genuine freedom presupposes a background engagement with the world that is not itself an exercise of freedom. If one seeks, as Sartre does, to find freedom in all acts of consciousness, one empties of any content the distinction between freedom and its absence by misconstruing the absence of a choice to act as a choice not to act. Instead, we need to acknowledge the impersonal significance of

things which arises from our sub-personal needs, habits and constraints; only against this background can a ‘strictly individual project’ stand out briefly as an exercise of freedom before its significance too is compromised by its incorporation into the general run of events.

5 Language

For many years Merleau-Ponty aimed to extend his account of our perception of ‘visible’ objects to an account of speech about ‘invisible’ truths (hence the title of his last book). His most extended discussion occurs in *The Prose of the World*, which was written in 1950-2, though published only posthumously. The central claim he makes here is that speech has a transcendental role comparable to that of perception in the constitution of truth. We normally fail to notice this because just as naïve perception encourages the realist illusion of perfect objectivity, our normal uses of language to talk about things encourage a similar realist illusion of language as a transparent vehicle for ready-made meanings. Once, however, we re-awaken an awareness of the genuine phenomenon of ‘speaking language’ within which meanings are forged, it becomes apparent that the expression of truths is a cultural achievement that is only sustained through the use of a common language. Indeed the fact that language is essentially common enables it to play a role comparable to that of the body in relation to perception; it is, Merleau-Ponty says, a form of ‘anonymous corporality’ ([1969] 1974: 140), and as such it sustains our a priori involvement with others in much the way in which our physical corporality sustains our a priori involvement with the physical world in perception. So, in enabling us to share our lives with others, language equally enables us to live in a world of shared, and thus objective, truths.

6 Painting

Merleau-Ponty applied his phenomenology to a great variety of subjects, including issues in history, sociology and politics; but his discussions of painting are especially interesting.

The classical painting of the Renaissance, he argues, with its perspectival delineation of distinct objects, is an art that is informed by the goal of capturing what is seen as the appearance of objects in their own right, related to the eye only in ways legitimated by an objectivist conception of the world. Impressionists such as Cézanne, by contrast, ‘did not want to separate the stable things which we see and the shifting way in which they appear; he wanted to depict matter as it takes on form’ ([1948] 1964: 13). Thus painters such as Cézanne, to whom Merleau-Ponty returns frequently, aim to capture on canvas the true phenomenology of the visual field. In their paintings the elements of the scene depicted emerge only through the interplay of often indistinct colours and shapes, sometimes unfolding without a single perspective; and yet ‘it is Cézanne’s genius that when the overall composition of the picture is seen globally, perspectival distortions are no longer visible in their own right but rather contribute, as they do in natural vision, to the impression of an emerging order’ ([1948] 1964: 14).

Similarly, one may say, it was Merleau-Ponty’s genius to see that when classical phenomenology is combined with psychological insight, a new way of thinking about human life emerges, one that can throw light on modern painting as much as on old questions of metaphysics.

Mersenne, Marin (1588-1648)

Marin Mersenne represents a new seventeenth-century perspective on natural knowledge. This perspective elevated the classical mathematical sciences over natural philosophy as the appropriate models of what can be known, of how it can be known and of the cognitive status of that knowledge. His early publications had the apologetic aim not only of combating various forms of heresy, but also of opposing philosophical scepticism, which was widely regarded in Catholic France of the early seventeenth century as undermining the certainty of religious dogma. To that end, Mersenne stressed the certainty of demonstrations in sciences such as optics, astronomy and mechanics, all of which stood as 'mathematical' sciences in the classifications of the sciences stemming from Aristotle. Mersenne's stress on the mathematical sciences contrasted them with natural philosophy in so far as the former concerned only the measurable external properties of things whereas the latter purported to discuss their inner natures, or essences. In accepting the considerable degree of uncertainty attending knowledge of essences, and juxtaposing it to the relative certainty of knowledge of appearances, Mersenne adopted a position (since called 'mitigated scepticism') that combated scepticism by lowering the stakes: in accepting that the essences of things cannot be known, he agreed with the sceptics; but in asserting that knowledge of appearances can, by contrast, be had with certainty, he rejected the apparent intellectual paralysis advocated by the sceptics. In furthering this programme, Mersenne embarked on a publication effort relating to the mathematical sciences, combined with a massive lifelong correspondence on largely philosophical as well as religious topics with a wide network of people throughout Europe.

1 Career and correspondence

Born in France at Oizé, Maine, Mersenne was educated at the Jesuit college of La Flèche soon after its foundation in 1604, where he was an older contemporary of Descartes. He left about 1609 to study theology in Paris at both the Sorbonne and the Collège de France. In 1611 he entered the austere Order of Minims, joining their Parisian convent off the Place Royale (now Place des Vosges) in 1619 where he lived for the rest of his life. His earliest publications date from 1623, and all have apologetic aims, culminating in *La verité des sciences* (1625). From 1626 onwards Mersenne's publications concentrated on the mathematical sciences, including the so-called 'mixed' mathematical sciences that concerned aspects of the physical world rather than simply pure quantity (whether discrete, as in arithmetic, or continuous, as in geometry). He is best known, perhaps, as Descartes' epistolary link to the learned world during the latter's residence in the Netherlands from 1629 until Mersenne's death; he assisted in the publication of Descartes' *Discourse on Method* (1637) and organized solicitation of the 'Objections' to the *Meditations* that appeared in 1641 (see Descartes, R. §1). In addition to Descartes, Mersenne corresponded with many other philosophers throughout Europe. He was the centre of an information network in which he acted as intelligencer and clearing-house, both communicating ideas and sometimes fomenting disputes. This tireless correspondence, amounting to seventeen volumes in its modern edition, has since earned him the label 'one-man scientific journal'.

The correspondence exemplifies aspects of Mersenne's wider religious and social concerns, in so far as it represents his increasing irenicism in the period following his early apologetic writings. Referred to late in his life as 'the Huguenot monk', Mersenne numbered Protestants as well as Catholics among his correspondents, and strove to overcome the doctrinal gaps between those camps. This generally took the form of gentle attempts at converting the Protestants to a moderate, reconciliatory form of Catholicism, and contrasts quite starkly with the ferocity of the assaults on heresy found in his early works. He never changed in his perception of the dangers of scepticism, however, and his so-called 'mitigated' scepticism amounted to a philosophical irenicism to match the religious. Mersenne's wide correspondence could itself proceed only within a broad discursive consensus, whether religious or philosophical.

Mersenne's engagement with the work of some of his illustrious philosophical contemporaries does not appear solely in relation to Descartes. During the 1630s, Mersenne publicized the work of Galileo with two books, as well as in occasional discussions of Galileo's work in other publications and in correspondence. Mersenne travelled several times, to the Netherlands (meeting Isaac Beeckman there), provincial France and Italy. From the latter excursion he brought back news to France, in 1645, of the Torricellian barometric experiment, which led to the famous work of Blaise Pascal on the weight of the air.

2 Apologetics and anti-scepticism

Mersenne's chief apologetic works contain a good deal of philosophical and mathematical content. They date from 1623, and include the recently rediscovered *L'Usage de la raison*, *Quaestiones celeberrimae in Genesim* and *Observationes et emendationes ad Francisci Georgii Venetii problemata* (generally bound together), *L'Impieté des deistes* (1624), and perhaps most significant, *La verité des sciences* (1625), a work that tackles the serious contemporary challenge of philosophical, particularly Pyrrhonian, scepticism with weapons drawn heavily from the mathematical sciences.

Quaestiones, his first major publication, is an uncompleted commentary on Genesis (a continuation exists in manuscript) containing lengthy digressions on such topics as astronomical systems and geometrical optics. Mersenne's ability to use such subject-matter for apologetic ends is typified by his use of optical theory to refute the naturalism of the sixteenth-century Paduan philosopher Pietro Pomponazzi. Naturalism was a doctrine that regarded nature as a self-activating, self-motivating system that had no need of the supernatural to sustain it. It thus seemed to Mersenne, as to many others, to reduce or eliminate the natural world's dependence on God's superintendence. There was an element of circularity in Pomponazzi's position, in so far as what counted as 'natural' was practically defined as whatever occurred in the natural world; thus, by definition, whatever happens is natural rather than miraculous or supernatural. For Pomponazzi and later proponents of this position such as the magician Julius Caesar Vanini (executed for heresy in 1619), even the miracles described in the Bible had been events with natural explanations. Pomponazzi had tried to account in terms of optical illusion for an angelic visitation recorded in the Old Testament. Mersenne responded by using his own knowledge of geometrical optics: he expatiates at length in *Quaestiones* on optics, and especially on the properties of curved mirrors, to show that Pomponazzi's explanation could not possibly work.

Mersenne soon extended the significance for religious apologetics of the so-called 'mixed' mathematical sciences (such as optics, astronomy, mechanics and music theory, which made use of theorems from geometry and arithmetic). This arose from his explicit confrontation of Pyrrhonian scepticism, a form of ancient Greek scepticism that enjoyed a revival starting around the middle of the sixteenth century. The central texts were writings by Sextus Empiricus (*c.*200 AD), including most famously his *Outlines of Pyrrhonism*. The Pyrrhonist maintained that no proposition could be held as absolutely certain - one could always find grounds, however outlandish, for doubt - and that, as a result, the wise man will always suspend judgment on all things, subscribing to no dogmatic beliefs, but simply conforming to prevailing norms. This position contrasts with so-called 'Academic' scepticism, also dating from antiquity, which recommended the exercise of probable judgment (see Pyrrhonism).

Pyrrhonism had become quite popular in some circles in France by the early seventeenth century, where it played a role in religious controversies. By the mid-1620s Mersenne had come to see it as just one example of a whole range of unorthodox philosophical positions that, like Pomponazzi's naturalism, threatened religious, and concomitantly social, stability. The most common tactic of its opponents in France at this time was to counter Pyrrhonian arguments piecemeal, precisely according to the form in which they were offered. Mersenne, by contrast, chose to attack Pyrrhonism by erecting an epistemological structure, with an associated natural philosophy, to act as a comprehensive bulwark; despite the later example of Descartes, reformulations of natural philosophy were not an inevitable tactic of opponents of Pyrrhonism in this period. A specific factor contributing to Mersenne's adoption of such an approach was his interest in natural philosophy and in the mathematical sciences.

For Mersenne, the problem with Pyrrhonism was not so much its use of sceptical arguments as the radical nature of the doubt that those arguments served to produce. Profound and generalized doubt came too close to promoting doubt in religion. Mersenne evidently thought that without the discipline of reason, heresy or unbelief would become too difficult to guard against. If scepticism were applied to sensitive areas like morality, it might not only promote immoral living, but also threaten social stability by questioning the principles on which social hierarchy was established. The difficulties therefore rested on the absoluteness of the challenge to certainty that Pyrrhonian scepticism posed. Mersenne responded by attempting to destroy the threat of total, universal doubt by establishing what might be called bridgeheads of certain knowledge, in the hope that these bridgeheads would prove sufficient to indicate a workable foundation for rational theology and rational, enforceable social order.

The main such bridgehead was that of the mathematical sciences. Mersenne had used the mathematical science of optics in *Quaestiones in Genesim* for apologetic purposes (to show the impossibility of naturalistic explanations of certain miracles), and its advantage there was one shared by all mathematical sciences: mathematics was conventionally treated as the exemplar of certain knowledge in contemporary school teachings, within a general context of a widespread moderate scepticism (greatly to be contrasted with the extremities of Pyrrhonism) promoted in the schools through the medium of humanist dialectic. This stressed the idea of probability rather than certainty in most practical affairs. Mersenne's Jesuit education had similarly emphasized the certainty of mathematics as a contrast to the merely probable knowledge available from qualitative Aristotelian physics. The author of the principal mathematical textbooks used in the Jesuit colleges, Christopher Clavius, tried to promote the status of the mathematical sciences in Jesuit pedagogy by exploiting the apparent contrast between the uncertainty of conclusions in natural philosophy and the certainty of those in mathematics, pointing out that a conclusion in dialectic 'is confirmed only probably', whereas a conclusion in mathematics is a matter of certain demonstration.

Mersenne's stance in *La verité des sciences* flows directly from this impact of humanist probabilism. One of the most characteristic aspects of his response to Pyrrhonian arguments regarding the uncertainty of most questions, and especially on the impossibility of achieving reliable knowledge of the essences of things, is that he generally *accepts* them. These were positions routinely accepted within early seventeenth-century scholastic natural philosophy. Mersenne departed from orthodoxy here only to the extent that his attempt to defeat Pyrrhonism required it. He did not absolutely reject any kind of knowledge that lacked absolute certainty; instead, he tended to discount it only because it did not serve his anti-Pyrrhonian argumentative strategy. He dismissed anything accepted as uncertain, so as to concentrate on the opportunities presented by what *was* certain; in practice, this tended to mean mathematics.

The certainty of mathematics would not in itself have been an adequate basis for an approach to *natural philosophy*. There were, in fact, three commonly-accepted sources of certainty recognized within mainstream humanist-influenced scholasticism by the early seventeenth century: mathematics, ordinary sense-perception and syllogistic logic. Although all three were themselves under fire from Pyrrhonist arguments, together they constituted the main ingredients of Mersenne's answer to Pyrrhonian scepticism. They worked together as interrelated elements of a form of natural philosophy that bypassed the essentialist claims of Aristotelianism. If accepted as reliable, ordinary sense-perception could serve to generate true statements whose consequences, through the application of syllogistic reasoning, might serve in turn to ground mathematical expressions of the appearances of things in the physical world. By a reversal of the process, mathematics then enables the determination of how sensory perceptions of appearances are affected by, or can be deliberately altered by, changes in circumstances or in the conditions of observation. Mersenne's proposal, therefore, is for a mathematical coordination of appearances, which can serve as an entirely satisfactory practical substitute for Aristotelian essentialist physics. Mersenne's prize examples of such a thing were, and remained, geometrical optics and music theory, although he also wrote on mechanics. The last took the form initially of quasi-Archimedean statics, although in the 1630s he took a considerable interest in Galileo's kinematics, an approach to change in the physical world that appealed greatly to Mersenne's project of modelling natural knowledge on the mathematical sciences.

An important aspect of Mersenne's approach is that of operationalism: being able to accomplish some practical task itself acts as a criterion of the possession of knowledge, much as we find in Francis Bacon (see Bacon, F. §3). This in turn indicates a positive evaluation of practical utility as a proper goal of philosophical knowledge. Once again, the theme of the utility of applied mathematics is recurrent in late fifteenth- and sixteenth-century humanist encomiums to mathematics, and forms a significant part of Clavius' defence of mathematical studies.

Richard H. Popkin (1979) has described Mersenne's overall position, as originally laid out in *La verité des sciences*, as 'constructive' or (following Hume) 'mitigated' scepticism. In Mersenne's form, however, it is less a grounded philosophical argument than the outcome of a particular set of philosophical assumptions deployed in a specific polemical context. Mersenne opposes to Pyrrhonism the position of Ciceronian humanist probabilism as widely promulgated in the schools, including the greatly influential Jesuit colleges. He thus emphasizes the kinds of knowledge that this position typically allowed as certain. Since these did not include essentialism - knowledge of the inner natures of things - as sought by (among other systems) Aristotelian natural philosophy, Mersenne

abandoned the latter, even while describing it as the ‘most probable’ such system. Since even a ‘probable’ essentialism was still open to the attacks of the Pyrrhonists precisely for not being certain (still the most important property of genuine knowledge, *scientia*), this left Mersenne upholding his favourite mathematical sciences as the models for a new natural philosophy.

Thus Mersenne should not be seen as substituting, like Descartes, a new philosophy in place of Aristotelianism, one that would be immune to the Pyrrhonist threat. Instead, he simply adapts most of the elements of his position from standard teachings, shifting the emphasis somewhat, in order to secure knowledge of nature (among other things) from Pyrrhonism. It would have been consistent with his arguments in *La verité* to have retained Aristotelian physics on a probabilistic basis. Indeed, his previous publications bear witness to just such a stance. But from *La verité* onwards, Mersenne effectively just ignores it in favour of mathematical sciences because physics implied knowledge of essences, and such knowledge was not certain - hence not an appropriate basis for a true science.

The philosophical inadequacy of Mersenne’s response to Pyrrhonism is made clear by the lack of arguments provided in support of the central planks of his position. Pyrrhonism questioned the reliability of ordinary sense-perceptions; Mersenne merely asserts it, and claims that variations in appearance - such as the standard example of a stick appearing bent when half-immersed in water - could be understood and coordinated through a proper understanding of the contingencies surrounding them (in the case of the stick, a proper understanding of refraction). This response, of course, begs the question of how assertions about refraction itself are to be grounded. Similarly, there were standard Pyrrhonian arguments against the value of syllogistic inference, relying especially on the point that syllogisms are question-begging because the universals on the basis of which they establish their singular conclusions are themselves justified on the basis of just such singulars. Mersenne is content to respond by reasserting the certainty of syllogistic inference and recommending the logical works of Aristotle for further elucidation. In the case of mathematics, for which Pyrrhonists also had a battery of undermining arguments, Mersenne does try a little harder, in particular defending arithmetic and geometry against some specific criticisms found in Sextus Empiricus.

Mersenne’s approach characterizes not just his lifelong opposition to extreme scepticism, but also his opposition to a variety of other deviant philosophies. That opposition had been manifested in previous writings (*Observationes*, directed especially against the recently executed magician Vanini, and the second volume of *L’Impieté des deistes*, which among other targets took on Giordano Bruno). He was also to engage in polemics with Robert Fludd slightly later in the 1620s. Although most of *La verité* takes the form of a dialogue between a ‘Christian Philosopher’ (evidently Mersenne’s mouthpiece) and a ‘Sceptic’ (the latter routinely being deeply impressed by the former’s display of mathematical truths), Book I, which contains most of the work’s philosophical meat, presents a three-way discussion. The additional interlocutor is the ‘Alchemist’. Mersenne’s trick is to allow the Sceptic freely to demolish the foundations of the Alchemist’s position (itself a variety of essentialism), and only when the Alchemist has been vanquished does the Christian Philosopher step in to show why the kind of knowledge that he prizes remains unthreatened by the criticisms directed at the Alchemist. Thus Mersenne’s selective acceptance of certain sceptical arguments flows not simply from his inability to refute them, but also from his wish to use them for his own ends. Orthodoxy was, for Mersenne, threatened more by magical and alchemical philosophies than it would be by the bracketing-off of essentialist Aristotelianism.

3 Mathematics and music

In practice, Mersenne’s work after 1625, both as a correspondent/intelligencer and as writer of books, focused on the promulgation of knowledge in the mathematical sciences and on the consideration of novelties in those fields. He is sometimes called a ‘mechanist’, a label reinforced by its use in the title of Robert Lenoble’s classic study *Mersenne ou la naissance du mécanisme* (1943). The usual understanding of that term for seventeenth-century philosophy is not properly applicable, however. Lenoble’s use of the term ‘mechanism’ equated it with instrumentalist, operational knowledge, whereas the usual meaning now among historians studying this period relates to specific *ontological* commitments, chief among them corpuscularianism or atomism. These stances, associated most closely with Descartes and Gassendi respectively, are of course essentialist, in that they make commitments to views on the underlying natures of things. In Descartes’ case the commitment, at this level of general matter-theory, was meant to be dogmatic rather than conjectural; in Gassendi’s, it was explicitly

hypothetical. But neither position seems to have appealed to Mersenne. His appreciation of sceptical views kept him from wholehearted acceptance of Cartesian mechanism, whereas his desire for certain knowledge made Gassendi's hypotheticalism unattractive. The model of the mixed mathematical sciences provided the perfect *via media*, since they neither committed to a particular ontological structure for the material world nor abandoned the goal of producing rigorous demonstrations of their conclusions.

His first publication specifically on the mathematical sciences was *Synopsis mathematica* (1626), a compendium of material on geometry, optics and also mechanics (a second edition appeared in 1644 under the title *Universae geometriae… synopsis*). In a similar vein he published *Les Mechaniques de Galilée* (1634e), a French paraphrase of an early Galilean work from the turn of the century on statics and simple machines, which had previously circulated only in manuscript; *Les Nouvelles pensées de Galilée* followed in 1638-9. The latter work presented paraphrased material from Galileo's 1638 *Discourses and Demonstrations Concerning Two New Sciences*, and provides further indication of the congeniality to Mersenne of Galileo's approach to issues of natural philosophy developed on the basis of 'mixed mathematics'.

Mersenne's first work devoted to music appeared in 1627, the *Traité de l'harmonie universelle*, on the heels of which he began composition of his great multi-volume *Harmonie universelle*, which finally appeared in 1636-7. These texts betray a further dimension of Mersenne's conception of mathematical knowledge and its relation to natural philosophy. He was much taken with Augustine's Neoplatonic emphasis on harmony as a foundational aspect of the created world's intelligibility. It is important to recall here that 'natural philosophy' in medieval and early-modern Latin culture was a branch of learning that treated the natural world as God's Creation. Music as a branch of mixed mathematics was concerned with ratios and proportions associated with certain privileged qualitative features of the world. It thus served to express the ineffable with mathematical precision. As a consequence, it was fit to act as the ideal basis for Mersenne's rather Augustinian conception of what he called 'universal harmony'. By seeing the constitution of the physical universe as being intelligible in the pre-established terms of musical ratios, Mersenne thought himself to have invested mathematical treatments of nature with genuinely natural-philosophical content. He attempted this extension by more than just drawing analogies or musical metaphors: he analysed the behaviour of balances in statics in terms of musical ratios, so as to represent their action as fulfilling precisely the same formal requirements as those of music, and completed the circle by representing musical consonances themselves as the product of the relative frequencies of series of air pulses. Indeed, in taking these latter as tantamount to sound itself, he went beyond the usual treatment, which usually only *correlated* sound with air disturbances, to *identify* sound with these mathematizable air pulses. He thus retained a kind of Platonic essentialism in his mathematical approach to physical phenomena.

Messer Leon, Judah (*c*.1425-*c*.1495)

*Messer Leon was a philosopher, physician, jurist, communal leader, poet and orator. Ordained as a rabbi by 1450, Messer Leon was qualified to adjudicate legal cases among Jews and head an academy (*yeshivah*) for advanced studies in Jewish law. He also came close to embodying the Renaissance ideal of* uomo universale. *His learning was formally recognized in 1469, when Emperor Frederick III awarded him a doctorate in medicine and philosophy and granted him the unusual privilege of conferring doctoral degrees in those subjects on Jewish students.*

Messer Leon's contribution to Jewish philosophy was in the field of logic, the art considered by him to be the key to the proper harmonization of religion and philosophy. He regarded scholastic logic to be superior to Arabic logic and wrote supercommentaries on Averroes' logical works as well as an encyclopedia of logic, Mikhlal Yofi (Purest Beauty), in an attempt to shift Jewish philosophical education from the Judaeo-Arabic logical tradition to scholastic logic. Although his encyclopedia became a popular textbook, Messer Leon failed to mould the culture of Italian Jewry as he had intended. In particular, he could not curb the spread of Kabbalah, a tradition which he vehemently opposed because of its underlying Platonic metaphysics.

Most importantly, Messer Leon composed the first manual of Hebrew rhetoric, entitled Nofet Tzufim (The Book of the Honeycomb's Flow). Printed in 1476, this Jewish response to Latin humanism combines the Averroist-Aristotelianism tradition and the Ciceronian-Quintilian one. The appropriation of humanistic rhetoric was given a Jewish meaning when Messer Leon claimed that the Torah, rather than the writings of the pagan, classical orators, exemplified perfect speech because it was a revelation of perfect divine wisdom. By analysing Scripture from the perspective of classical rhetoric, Messer Leon legitimized the study of ancient pagan and Christian orators even as he argued for the supremacy of biblical rhetoric over all merely human eloquence.

1 Life and works

Rabbi Judah ben Yehiel, called Messer Leon, wrote philosophic and scientific works in Hebrew to afford his *yeshivah* students university-level instruction, from which all but a tiny fraction of Jews were excluded. He lived in Ancona, Mantua, Padua, Bologna, Venice and Naples, always relocating his celebrated *yeshivah* wherever he went. Linked by kinship and business ties to Jewish banking families (the Da Pisas of Florence and the Norsas of Mantua) and honoured by titles and privileges in the Jewish and larger Italian community, Messer Leon without question enjoyed the highest social status held by a Jew in Renaissance Italy. He came to think of himself as the leader of Italian Jewry and issued decrees intended to shape Jewish religious practice, belief, and education. He even adopted the ancient title *Ro'sh Golah* (Head of the Diaspora). But his aristocratic pretensions were resented by other rabbis, and his attempts to lead all Italian Jews were hardly universally accepted. The time and place of his death are uncertain, but it is unlikely that he survived the conquest of Naples by the French armies of Charles VIII in 1494/5.

Deeply rooted in scholastic Aristotelianism and staunchly loyal to Maimonides, the paramount figure in medieval Jewish Aristotelianism, Messer Leon saw philosophy as dedicated to the elucidation of authoritative texts. He was dedicated to logic and convinced that reasoning could resolve the apparent conflict between religion and philosophy. Trained by Christian logicians, he found scholastic logic superior to the Arabic logic taught by al-Farabi and Averroes (see Ibn Rushd). Seeking to shift Jewish philosophical training to the Latin model, he wrote supercommentaries on Averroes' middle commentaries on the Organon, painstakingly collating their diverse textual traditions and harmonizing the Hebrew versions with the diverse Latin readings.

His 1454 compendium of Aristotelian logic, entitled *Mikhlal Yofi (Purest Beauty)*, departed from medieval Arabic precedent by omitting the *Rhetoric* and *Poetics*, in effect emancipating these studies from their medieval status as mere arts of persuasion. *Mikhlal Yofi* excerpted several books of scholastic logic, notably the *Logica magna* of Paul of Venice (*circa*1339/72-1429), which was also the primary source of Messer Leon's supercommentary on the *Posterior Analytics*. His supercommentary on Porphyry's *Isagōgē*, similarly, drew heavily on the *Super artem veterem expositio* of Walter Burley (*circa* 1275-1345). The supercommentaries on *Categories*, *De interpretatione* and the *Prior Analytics*, all extant in manuscripts, again rely on scholastic sources. Usefully, Messer Leon wrote summaries (*sefeqot*) of the major philosophical questions debated in Italian universities.

His debt to scholastic authors led to charges by a philosophy instructor in his own *yeshivah*, now known only as David the Spaniard, that his writings were mere translations and that even his glosses bordered on plagiarism. The master publicly rebutted the accusations and dismissed his adversary as a exponent of the views of Jewish Averroists from Provence, chiefly, Levi ben Gershom (see Gersonides), whose apparent denial of God's knowledge of particulars seemed to undermine the idea of providence. Messer Leon tried to suppress Gersonides' recently printed commentary on the Pentateuch, but with little success. It was highly esteemed among native Italian Jews, and Gersonides' *magnum opus*, *Milhamot ha-Shem (The Wars of the Lord)*, became a classic of Jewish philosophy among the educated.

2 Philosophical standpoint

The extant works and the letters of Messer Leon's son David (d. *circa* 1535), cite a number of philosophical and scientific works now lost: supercommentaries on Aristotle's *On the Soul*, *Metaphysics*, *Nicomachaean Ethics*, *Physics* and, possibly, the *Topics*. To prepare his students in medicine, he wrote a commentary on the first and second parts of Avicenna's *Canon*, and a short summary of essential medical information (*Yedi'ot ha-nehuzot le-Rofe'*). Despite his devotion to such studies, Messer Leon, like the medieval Jewish philosophers, did not view philosophy and its allied arts and sciences as ends in themselves, but saw them as preparation for higher study - of the divinely revealed religion. In keeping with his desire to articulate an official Jewish theology, he commented on the two most widely read texts of Jewish philosophy in fifteenth-century Italy: Maimonides' *Guide to the Perplexed* and Yeda'aya Bedersi's *Behinat 'Olam (Examination of the Universe)*. The *Moreh Tzedeq (Teacher of Righteousness)*, his commentary on the *Guide*, is now lost, but his commentary on *Behinat 'Olam* is extant in several manuscripts and awaits systematic study. A reading of it shows Messer Leon's kinship in approach to other Jewish Aristotelians of his time. Like Joseph Ibn Shem Tov (d. *circa* 1460), Abraham Bibago (d. *circa* 1489) and Abraham Shalom (d. *circa* 1492) in Spain, and Elijah Delmedigo (d.1493) in Crete and Italy, Messer Leon insisted on the rationality of a divinely revealed Judaism while recognizing the inherent limitations of natural human reason. Because philosophic understanding rests on sense perception, it is prone to errors, doubts, and uncertainties and cannot bring us to our ultimate goal, individual beatitude in the hereafter. It must be complemented by revealed truths beyond the ken of natural reason. But these suprarational truths cannot contradict the precepts of philosophy. A rational examination of Judaism, which Messer Leon apparently undertook in his now lost commentary on the Pentateuch, would show that the Torah of Moses is in full accord with the teachings of Aristotle, as properly understood.

3 Rhetoric

Messer Leon endorsed the Platonic elitism of the Maimonidean tradition: God's revelation is abstruse; ordinary people lack the intellectual perfection needed to grasp its truths directly. They must receive these through the veils of figurative language. But philosophical wisdom does grasp the inner meaning of the Torah, and this more penetrating understanding of the Torah's message and its tropes endows the philosopher with political authority - an authority that rests on exegesis, and so on the study of grammar and rhetoric.

Messer Leon's *Livenat ha-Sappir (The Sapphire Stone)* systematically applied the categories of European grammar to the Hebrew language. The work relied heavily on the writings of Abraham ibn Ezra (1089-1164). Distinctive in Messer Leon's approach was the influence of Renaissance humanism (see Humanism, Renaissance). He saw grammar not merely as ancillary to logic but as praiseworthy in its own right. Its kinship with rhetoric made it an essential tool of cogent argument and elegant exposition and a *sine qua non* in exegesis.

In 1475, in Mantua, Messer Leon published a manual of Hebrew rhetoric entitled *Nofet Tzufim*, taking his title from the Psalms, where the image is applied to God's speech. Like his works on logic, this inventory of linguistic tropes combined Arabic and Latin traditions: the Averroist-Aristotelian tradition he knew through Todros Todrosi's Hebrew translation of Averroes' middle commentary on Aristotle's *Rhetoric*, and the Ciceronian-Quintilian tradition, which he knew chiefly through the pseudo-Aristotelian *Rhetorica ad Alexandrum*, Cicero's *De inventione*, the pseudo-Ciceronian *Rhetorica ad Herennium*, Quintialian's *Institutio oratoria*, and Marius Victorinus' commentary on Cicero's *De inventione*.

The first articulate Jewish response to the humanist cult of rhetoric and the concomitant revival of classical prose and poetry, *Nofet Tzufim* sparked a new appreciation for eloquence among Italian Jewish scholars. Siding with

Ermolao Barbaro in his dispute with Giovanni Pico della Mirandola, Messer Leon prized eloquence as a complement to moral and intellectual perfection: a good orator must first be a good man and a good philosopher. In place of the 'golden age' Latin held up as a model by Renaissance writers, Messer Leon placed biblical Hebrew, the perfect exemplar of the Ciceronian ideal of a synthesis of wisdom with eloquence (see Cicero, M.T.). By analysing Scripture in this Ciceronian light, Messer Leon legitimized the study of ancient pagan and Christian orators even as he argued for the supremacy of biblical rhetoric over all merely human eloquence.

4 Humanism and Kabbalah

The Renaissance humanism he so admired presented Messer Leon with an acute political and intellectual problem. The humanists of the later fifteenth century, especially in the Platonic Academy of Florence, revived numerous non-Aristotelian cosmological constructs, including Platonic, Neoplatonic and Hermetic frameworks. Urging the unity of all truth, humanists like Marsilio Ficino and Pico della Mirandola sought an ancient syncretic wisdom in these religious and philosophic traditions. A vital part of the *prisca theologia* they sought was the Jewish esoteric and mystical tradition of Kabbalah (see Kabbalah). The humanists' deep respect for Kabbalah contrasted sharply with the disdain of medieval scholars towards rabbinic Judaism, but it was not devoid of missionarizing intent. For the syncretic tradition was seen as culminating in Christianity; and, among the many Jewish intellectuals drawn by the humanist revival of Platonism and fascination with Kabbalah, some became converts to Christianity.

Messer Leon attempted to stem the spread of Kabbalah in Italy, viewing the tradition as neither authentic nor authoritative *vis-à-vis* rabbinic Judaism. It was a mere medieval throwback, a human innovation closely akin to the inferior philosophy of Platonism, which compromised the absoluteness of God's unity and incorporeality. Distressed in particular by the Christian overtones of humanist interest in Kabbalah, Messer Leon forbade its study in his *yeshivah*, but he had little success in curbing its spread in Italy among Jews and non-Jews alike. His son David and two other students of Aristotelian philosophy, Yohanan Alemanno (d. after 1503/4) and Abraham de Balmes (d. 1523), cultivated the Kabbalah and sought to incorporate its doctrines into the framework of Jewish Aristotelianism.

Messer Leon played an essential role in keeping alive the traditions of medieval Aristotelian philosophy among Italian Jews in the later fifteenth century. Modelling the training in his *yeshivah* on the Italian university curriculum, he professionalized the study of philosophy among Italian Jews. His sensitivity to humanist ideals enabled him to create a cadre of Jewish scholars who could offer spiritual leadership and eloquent counsel to the Jewish community. But all his high-handed attempts to mould the culture of Italian Jewry failed. His own students did not accept his categorical preference for Aristotelian logic over Platonic metaphysics, and even his son did not follow him in rejecting Kabbalah. Sixteenth-century Italian Jewish scholars were increasingly influenced by Renaissance Platonism and Kabbalah, rather to the cost of Maimonidean rationalism, as the accepted theology of Judaism.

Metaphor

A standard dictionary definition describes a metaphor as 'a figure of speech in which a word or phrase literally denoting one kind of object is used in place of another to suggest a likeness between them'. Although the theoretical adequacy of this definition may be questioned, it conveys the standard view that there is a difference between literal and nonliteral language; that figurative speech is nonliteral language and that a metaphor is an instance of figurative speech.

The three most influential treatments of metaphor are the comparison, interaction and speech act theories. According to the first, every metaphor involves a comparison; a specific version of this view is that every metaphor is an abbreviated simile. According to the second, every metaphor involves a semantic interaction between some object or concept that is literally denoted by some word, and some concept metaphorically predicated on that word. According to the third, it is not words or sentences that are metaphorical but their use in specific situations; thus, to understand how metaphors function, one must understand how people communicate with language.

1 The comparison theory

The comparison theory asserts that every metaphor compares two things, one of which is designated by a word or phrase used literally and the other of which is designated by a word or phrase used metaphorically. The most interesting version of the comparison view of metaphor is the simile theory. According to its originator, Aristotle (*Rhetoric* III.4), a metaphor is an abbreviated simile: the sentence 'My lover is a red rose' is shorthand for 'My lover is like a red rose'. (The simile theory is also sometimes known as the abbreviation or substitution theory, because a metaphor is represented as being an abbreviation of or a substitution for a simile.) The merit of this view is its double simplicity. First, what looked like two things (metaphors and similes) are said to be one thing; second, the analysis that is given to similes is sometimes quite simple. A simile is true just in case there is some feature that each object has. The feature common to both constitutes the similarity.

One objection to this theory is that what has been represented as its first merit is in fact a misrepresentation. Metaphors and similes are different things because typically if a metaphor were literally asserted, the result would be a falsehood, while (virtually) all similes are true. For example, the metaphor 'My lover is a red rose' is literally false, while the simile 'My lover is like a red rose' is literally true. The pretence of saying something false is a crucial feature of how metaphors work. To hold that metaphorical sentences are in fact similes obscures this feature. This is not to deny that metaphors typically communicate a truth in some way; it is rather to hold that a metaphor communicates its truth in a different way to a simile.

Metaphors (unlike similes) do not state or express truths; they imply them. In order to speak truly, the words of a sentence must be conventionally or semantically appropriate to each other, but the words of a metaphor are not semantically appropriate in this sense. For example, in the metaphor 'Sally is a block of ice', 'Sally' and 'a block of ice' belong to categories so different that to juxtapose them results not merely in a falsehood but in an absurdity. Someone may reply that, since 'Sally is a block of ice' can be used metaphorically, 'Sally is not a block of ice' can also be used metaphorically; and since this latter metaphor results in a true assertion, its words cannot be semantically inappropriate to each other. The proper reply to this objection is to deny that 'Sally is not a block of ice' is a metaphor. (To assert it is to assert something that is obviously true, but that does not mean that the assertion is pointless any more than to assert that 'Business is business' need be pointless. To assert that 'Sally is not a block of ice' may imply that one rejects the metaphorical utterance of 'Sally is a block of ice'.) Sentences that may appear to be negations of metaphorical sentences, such as John Donne's memorable sentiment 'No man is an island', are simply instances of *meiosis* (intentionally saying something logically weaker than the speaker intends to convey, usually by using a negative). Philosophers who consider 'No man is an island' and 'Sally is not a block of ice' to be metaphors, are in effect conflating metaphor and meiosis. They make it difficult or impossible to distinguish something obviously, literally false ('Business is theft') from something obviously, literally true ('Business is business').

To deny an assertion is *ipso facto* to make an assertion; but to deny a metaphor is not to make a metaphor. Assertions are a type of speech act, performed through a literal use of words. But a metaphor is not a kind of

speech act and relies on the literal use of words only in order to indicate that the speaker means to communicate something other than their literal meaning.

Another deficiency of the standard simile theory is that it does not account for the fact that some effort or mental computation is required in order to work out what a metaphor means, in contrast with a simile which usually means what it says. In order to meet this objection, a quasi-simile theory has been proposed. Suppose someone says ‘My lover is a red rose’. To understand this metaphor, one considers the set of red roses plus the speaker’s lover and then tries to work out which property or properties all the members of this set share; in other words, to say that one’s lover is a red rose is to say that they are similar in some respects to red roses. The objection to this theory is the same as one raised to the original theory. As Davidson (1979: 36) points out, a metaphor only intimates what a simile declares.

2 The interaction theory

According to the interaction theory, a metaphor involves an interaction between a literal element in a sentence and a metaphorical element. So there are always two parts to a metaphor. Max Black (1962) calls the literal element the frame and the metaphorical element the focus. Searle (1979) has effectively refuted this version of the theory by pointing out that some metaphorical sentences do not contain any literal element which could plausibly serve the role of frame. For example, the sentence ‘The bad news congealed into a block of ice’ is a mixed metaphor, but it contains no word with a literal meaning that can serve as the frame. Another objection to the interaction theory is that the term ‘interaction’ is itself a metaphor. Since there is no literal interaction between words in a sentence or between concepts, the interaction theory never actually explains or describes how metaphors work. More recent treatments of the theory explain interaction as the placement of the object literally denoted within a conceptual system of commonplaces associated with the metaphorical term. Thus, to say ‘Mary is a wolf’ is to associate Mary and her attributes with the complex of properties associated with wolves: cunning, viciousness, unpredictability and so on. None the less ‘interaction’ seems to be the wrong word to convey this feature. Also, the interaction theory claims that the meaning of the words is affected by this interaction and that seems to be an inaccurate description of the phenomenon.

Donald Davidson has insisted that semantically metaphors mean what the words used to convey them literally mean and nothing more. His thesis constitutes a direct rejection of all views that hold that a distinction must be drawn at the level of words or sentences between two kinds of meaning: literal meaning and metaphorical meaning. While the literal meaning is usually taken as obvious, the metaphorical meaning is often said to be ineffable and ineffability is given as the reason why metaphors are used. Sceptics about ineffability would object to a kind of meaning that is inherently mysterious or unintelligible, even if individual speakers are unable to articulate what they mean. In any case, what is needed is an explanation of how metaphors are understood. Here, Davidson seems to be right when he says that understanding a metaphor is the same kind of activity as understanding any other linguistic utterance and all understanding requires an ‘inventive construal’ of what the literal meaning of the metaphorical utterance is and what the speaker believes about the world. Furthermore, this activity is ‘little guided by rules’. Making a metaphor, like speaking generally, is a ‘creative endeavour’.

3 The speech act theory

It is fair to demand that a theory of metaphor fit into some larger theory of language or communication. While the comparison and interaction theories do not meet this demand, the speech act theory does. H.P. Grice (1989) distinguished between ‘utterance occasion meaning’ (the meaning that an utterance has on some particular occasion of its use) and ‘timeless utterance meaning’ (the meaning an utterance has based upon its usual use and independent of any particular time). This latter form of meaning can be associated with literal or conventional meaning. In a metaphor, the speaker intends to have the audience work out the ‘occasion’ meaning of their utterance in part by understanding its ‘timeless’ meaning (see Grice, H.P.).

How does this happen? Grice points out that normal conversation is directed by the cooperative principle: make your contribution to a conversation appropriate. This principle issues in various conversational maxims. For example, what a person says should be truthful and supported by evidence; it should be as informative as the audience needs it to be and not more so; and the information should be relevant to the topic of conversation. These maxims are related to the content of the message. There are also maxims concerning how the message is to be

expressed: it should be clear, unambiguous, brief and orderly. Of course these maxims are not always fulfilled. Sometimes they go unfulfilled quietly and unostentatiously, such as when a person lies or makes an innocent mistake. Sometimes they are flouted, that is, openly and ostentatiously unfulfilled in order to achieve a certain effect. For example, one way to show disgust for or disappointment with someone is to say ‘You’re a fine friend’. In such instances of sarcasm or irony, the speaker flouts the maxim of truthfulness and thereby within the context of the conversation means exactly the opposite of what appears to be said. Other figures of speech can be explained in similar ways. Hyperbole is intentionally making an exaggerated statement in order to achieve a certain effect. Within the theory being sketched, hyperbole is also achieved by flouting the maxim of truthfulness: the speaker makes a statement that is logically stronger than the proposition they intend to communicate.

Within this theory, meiosis is achieved by flouting the maxim of quantity (which enjoins the speaker to make their statement logically as strong as possible); for example, by saying, ‘John D. Rockefeller was not poor’. The audience, trying to make sense of the speaker’s apparent nonfulfilment of the cooperative principle, infers that the speaker means something stronger than was said.

Metaphor fits into the same pattern of explanation although the calculation of what a metaphor means is more complicated. If someone says ‘My lover is a red rose’ in circumstances that are otherwise unexceptional, it is sensible for the audience to judge that the speaker is flouting the maxim of truthfulness. What then does the speaker mean? The audience’s strategy in the case of metaphor, as in every other case of linguistic understanding, is to achieve a cognitive equilibrium by accepting those propositions that make the most sense of the situation. This involves making new beliefs fit in as smoothly as possible with existing beliefs and sometimes revising old beliefs as part of this process. Briefly, for the example above, it makes sense for the audience to believe that the speaker intends the audience to recognize that the speaker intends the audience to think of certain qualities of a rose - its beauty, value, delicacy, fragrance - and then attribute them to the lover. Such a search for cognitive equilibrium is close to what Davidson meant when he said that understanding language is ‘a creative endeavour’.

Metaphysics

Metaphysics is a broad area of philosophy marked out by two types of inquiry. The first aims to be the most general investigation possible into the nature of reality: are there principles applying to everything that is real, to all that is? - if we abstract from the particular nature of existing things that which distinguishes them from each other, what can we know about them merely in virtue of the fact that they exist? The second type of inquiry seeks to uncover what is ultimately real, frequently offering answers in sharp contrast to our everyday experience of the world. Understood in terms of these two questions, metaphysics is very closely related to ontology, which is usually taken to involve both ‘what is existence (being)?’ and ‘what (fundamentally distinct) types of thing exist?’ (see Ontology).

The two questions are not the same, since someone quite unworried by the possibility that the world might really be otherwise than it appears (and therefore regarding the second investigation as a completely trivial one) might still be engaged by the question of whether there were any general truths applicable to all existing things. But although different, the questions are related: one might well expect a philosopher’s answer to the first to provide at least the underpinnings of their answer to the second. Aristotle proposed the first of these investigations. He called it ‘first philosophy’, sometimes also ‘the science of being’ (more-or-less what ‘ontology’ means); but at some point in antiquity his writings on the topic came to be known as the ‘metaphysics’ - from the Greek for ‘after natural things’, that is, what comes after the study of nature. This is as much as we know of the origin of the word (see Aristotle §11 and following). It would, however, be quite wrong to think of metaphysics as a uniquely ‘Western’ phenomenon. Classical Indian philosophy, and especially Buddhism, is also a very rich source (see Buddhist philosophy, Indian; Hindu philosophy; Jaina philosophy).

1 General metaphysics

Any attempt on either question will find itself using, and investigating, the concepts of being and existence (see Being; Existence). It will then be natural to ask whether there are any further, more detailed classifications under which everything real falls, and a positive answer to this question brings us to a doctrine of categories (see Categories). The historical picture here is complex, however. The two main exponents of such a doctrine are Aristotle and Kant. In Aristotle’s case it is unclear whether he saw it as a doctrine about things and their basic properties or about language and its basic predicates; whereas Kant quite explicitly used his categories as features of our way of thinking, and so applied them only to things as they appear to us, not as they really or ultimately are (see Kant, I.). Following on from Kant, Hegel consciously gave his categories both roles, and arranged his answer to the other metaphysical question (about the true underlying nature of reality) so as to make this possible (see Hegel, G.W.F.).

An early, extremely influential view about reality seen in the most general light is that it consists of things and their properties - individual things, often called particulars, and properties, often called universals, that can belong to many such individuals (see Particulars; Universals). Very closely allied to this notion of an individual is the concept of substance, that in which properties ‘inhere’ (see Substance). This line of thought (which incidentally had a biological version in the concepts of individual creatures and their species) gave rise to one of the most famous metaphysical controversies: whether universals are real entities or not (see Species; Natural kinds). In different ways, Plato and Aristotle had each held the affirmative view; nominalism is the general term for the various versions of the negative position (see Nominalism).

The clash between realists and nominalists over universals can serve to illustrate a widespread feature of metaphysical debate. Whatever entities, forces and so on may be proposed, there will be a *prima facie* option between regarding them as real beings, genuine constituents of the world and, as it were, downgrading them to fictions or projections of our own ways of speaking and thinking (see Objectivity; Projectivism). This was, broadly speaking, how nominalists wished to treat universals; comparable debates exist concerning causality (see Causation), moral value (see Emotivism; Moral realism; Moral scepticism; Value, ontological status of) and necessity and possibility (see Necessary truth and convention) - to name a few examples. Some have even proposed that the categories (see above) espoused in the Western tradition are reflections of the grammar of Indo-European languages, and have no further ontological status (see Sapir-Whorf hypothesis).

Wittgenstein famously wrote that the world is the totality of facts, not of things, so bringing to prominence another concept of the greatest generality (see Facts). Presumably he had it in mind that exactly the same things, differently related to each other, could form very different worlds; so that it is not things but the states of affairs or facts they enter into which determine how things are. The apparent obviousness of the formula 'if it is true that *p* then it is a fact that *p*', makes it seem that facts are in one way or another closely related to truth (see Truth, coherence theory of; Truth, correspondence theory of) - although it should be said that not every philosophical view of the nature of truth is a metaphysical one, since some see it as just a linguistic device (see Truth, deflationary theories of) and some as a reflection, not of how the world is, but of human needs and purposes (see Truth, pragmatic theory of; Relativism).

Space and time, as well as being somewhat elusive in their own nature, are further obvious candidates for being features of everything that exists (see Space; Time). But that is controversial, as the debate about the existence of abstract objects testifies (see Abstract objects). We commonly speak, at least, as if we thought that numbers exist, but not as if we thought that they have any spatio-temporal properties (see Realism in the philosophy of mathematics). Kant regarded his things-in-themselves as neither spatial nor temporal; and some have urged us to think of God in the same way (see God, concepts of). There are accounts of the mind which allow mental states to have temporal, but deny them spatial properties (see Dualism).

Be all this as it may, even if not literally everything, then virtually everything of which we have experience is in time. Temporality is therefore one of the phenomena that should be the subject of any investigation which aspires to maximum generality. Hence, so is change (see Change). And when we consider change, and ask the other typically metaphysical question about it ('what is really going on when something changes?') we find ourselves faced with two types of answer. One type would have it that a change is an alteration in the properties of some enduring thing (see Continuants). The other would deny any such entity, holding instead that what we really have is merely a sequence of states, a sequence which shows enough internal coherence to make upon us the impression of one continuing thing (see Momentariness, Buddhist doctrine of). The former will tend to promote 'thing' and 'substance' to the ranks of the most basic metaphysical categories; the latter will incline towards events and processes (see Events; Processes). It is here that questions about identity over time become acute, particularly in the special case of those continuants (or, perhaps, processes), which are persons (see Identity; Persons; Personal identity).

Two major historical tendencies in metaphysics have been idealism and materialism, the former presenting reality as ultimately mental or spiritual, the latter regarding it as wholly material (see Buddhism, Yogācāra school of; Idealism; Materialism; Materialism in the philosophy of mind; Monism, Indian; Phenomenalism). In proposing a single ultimate principle both are monistic (see Monism). They have not had the field entirely to themselves. A minor competitor has been neutral monism, which takes mind and matter to be different manifestations of something in itself neither one nor the other (see Neutral monism). More importantly, many metaphysical systems have been dualist, taking both to be fundamental, and neither to be a form of the other (see Sāōkhya). Both traditions are ancient. In modern times idealism received its most intensive treatment in the nineteenth century (see Absolute, the; German idealism); in the second half of the twentieth century, materialism has been in the ascendant. A doctrine is also found according to which all matter, without actually being mental in nature, has certain mental properties (see Panpsychism).

2 Specific metaphysics

There is also metaphysics that arises in reference to particular subject matters, this being therefore metaphysical primarily with regard to the second question (what are things ultimately like? - or, what kinds of thing ultimately exist?) rather than the first. One of the most obvious cases, and historically the most prominent, is theology; we have already mentioned the philosophy of mind, the philosophy of mathematics and the theory of values. Less obviously, metaphysical issues also intrude on the philosophy of language and logic, as happens when it is suggested that any satisfactory theory of meaning will have to posit the existence of intensional entities, or that any meaningful language will have to mirror the structure of the world (see Intensional entities; Logical atomism). The political theorist or social scientist who holds that successful explanation in the social sphere must proceed from properties of societies not reducible to properties of the individuals who make them up (thereby making a society an entity that is in a sense more basic than its members) raises a metaphysical issue (see Holism and individualism

in history and social science). Metaphysics, as demarcated by the second question, can pop up anywhere.

The relationship with metaphysics is, however, particularly close in the case of science and the philosophy of science. Aristotle seems to have understood his ‘first philosophy’ as continuous with what is now called his physics, and indeed it can be said that the more fundamental branches of natural science are a kind of metaphysics as it is characterized here. For they are typically concerned with the discovery of laws and entities that are completely general, in the sense that everything is composed of entities and obeys laws. The differences are primarily epistemological ones, the balance of a priori considerations and empirical detail used by scientists and philosophers in supporting their respective ontological claims. The *subject matter* of these claims can even sometimes coincide: during the 1980s the reality of possible worlds other than the actual one was maintained by a number of writers for a variety of reasons, some of them recognizably ‘scientific’, some recognizably ‘philosophical’ (see Possible worlds). And whereas we find everywhere in metaphysics a debate over whether claims should be given a realist or an antirealist interpretation, in the philosophy of science we find a parallel controversy over the status of the entities featuring in scientific theories (see Realism and antirealism; Scientific realism and antirealism).

It is true that there has been considerable reluctance to acknowledge any such continuity. A principal source of this reluctance has been logical positivism, with its division of propositions into those which are empirically verifiable and meaningful, and those which are not so verifiable and are either analytic or meaningless, followed up by its equation of science with the former and metaphysics with the latter (see Demarcation problem; Logical positivism; Meaning and verification). When combined with the belief that analytic truths record nothing about the world, but only about linguistic convention, this yields a total rejection of all metaphysics - let alone of any continuity with science. But apart from the fact that this line of thought requires acceptance of the principle about meaninglessness, it also makes a dubious epistemological assumption: that what we call science never uses non-empirical arguments, and that what we regard as metaphysics never draws on empirical premises. Enemies of obscurantism need not commit themselves to any of this; they can recognize the continuity between science and metaphysics without robbing anyone of the vocabulary in which to be rude about the more extravagant, ill-evidenced, even barely meaningful forms which, in the view of some, metaphysics has sometimes taken.

Even the philosopher with a low opinion of the prospects for traditional metaphysics can believe that there is a general framework which we in fact use for thinking about reality, and can undertake to describe and explore it. This project, which can claim an illustrious ancestor in Kant, has in the twentieth century sometimes been called descriptive metaphysics, though what it inquires into are our most general patterns of thought, and the nature of things themselves only indirectly, if at all. Though quite compatible with a low estimate of traditional metaphysics as defined by our two primary questions, it does imply that there is a small but fairly stable core of human thought for it to investigate. Hence it collides with the view of those who deny that there is any such thing (see Postmodernism).

Methodological individualism

Methodological individualism (MI) is the thesis that certain psychological properties are intrinsic *properties, such as 'being made out of iron', rather than externally* relational *properties, such as 'being an aunt'. It has been challenged by influential 'anti-individualist' claims of, for example, Putnam and Burge, according to which the content of an individual's words or thoughts (beliefs, desires) is determined in part by facts about their social or physical environment. Putnam, for example, imagines a planet, 'twin earth', which is identical to the earth in 1750 (prior to modern chemistry) in all respects except that wherever earth had H_2O, twin earth had a different but superficially similar chemical, XYZ. Putnam argues that the English word 'water' in 1750 referred only to H_2O, while the twin word 'water' refers only to XYZ.*

Historically, the term 'methodological individualism' has referred to the thesis that all social explanation must be ultimately expressible in terms of facts about individual human beings; not about economic classes, nations and so on. For a treatment of this subject, see Explanation in history and social science §1.

1 Common arguments for MI

Methodological individualism (MI) is a view about the representational contents of psychological states. There is a distinction between two kinds of such contents: narrow and wide (see Content: wide and narrow). A content is 'wide' if its identity depends upon relations its thinkers bear to things outside their heads. Suppose, for example, that I am looking at a particular banana, *B*, and I think 'That banana is ripe'. My thought is then about that object, *B*. The thought is true if and only if *B* is ripe. In that sense, the content of the thought relates essentially to the banana itself. Had there been a different banana, *A*, my thought would have had a different content: it would have been true if and only if *A* had been ripe.

Content is 'narrow' if it is not relational, but is instead fully determined by intrinsic physical properties of individuals. Thus, any two individuals who were identical in all intrinsic physical respects would be identical in respect of all their narrow contents. Call such individuals 'twins'. Narrow content is content shared by twins (see Identity of indiscernibles §3). The above example of 'twin earth', due to Putnam (1975), challenges the view that the ordinary content we ascribe to people is narrow in this sense: the thought contents expressed by 'Water is wet' by the 1750 earthling and their twin-earthling would seem to be different, the first making a claim about H_2O, the second about XYZ.

MI is the view that, despite such twin cases, every psychological state has a narrow content, and that this content is, or should be, essential for psychological explanations. Thus, consider a pair of twins one of whom is thinking about banana *A* and the other about banana *B*. Each thinks 'That banana is ripe'. The methodological individualist will claim that the two thoughts have a content in common; a narrow content. They concede that the thoughts are about different external objects, but hold that the concepts involved - one twin's concept of *A* and the other's concept of *B* - are exactly the same. And this shared content, the one that includes exactly similar concepts, is crucial to psychological explanation. The same applies to Putnam's twins: their thoughts also have a shared narrow content.

Anti-individualists have presented three kinds of argument to show that contents attributed by both common sense and scientific psychological theory are wide rather than narrow. The first of these involves thought experiments, like Putnam's, in which one conceives of twins who inhabit environments that differ in crucial respects, and it is claimed that there is a strong intuition that the individuals' psychological states would have different contents. The second defends wide content on the basis of independently motivated theories of content, such as causal or teleo-functional theories (see Semantics, teleological; Semantics, informational). The third flow from studies of specific branches of scientific psychology. Since the first two kinds of argument are treated in other entries, the present entry will discuss only the third, considering the question of whether contents attributed by scientific psychology are narrow or wide.

2 MI and the causal role of psychological properties

Jerry Fodor (1987) gives the following argument for MI.

(1) Psychological explanation is causal explanation. For example, we might cite someone's belief that water is good for plants as part of a causal explanation of why they filled a watering-can.
(2) A science that offers causal explanation individuates its subject matter with respect to causal powers. Specifically, it would not classify states as being of different kinds if they have the same causal powers.
(3) The causal powers of the psychological states of twins are the same. So, psychology would classify twins' psychological states as being of the same kind, hence as having the same content.

This argument may be questioned on various grounds (see, for example, Burge (1986); Fodor (1994), who has himself abandoned it). For example, the second premise is not obviously correct. The individuative practice of a science that offers causal explanations might be sensitive to various factors, not all of which are directly relevant to causal powers. For instance, a scientist might cite the action of the heart as part of a causal explanation of the workings of the cardiovascular system. However, the individuation conditions for hearts are not purely causal, but also involve historical, evolutionary considerations. Nevertheless, Fodor's argument has been influential, and methodological individualists may feel that there is something importantly right about it, even if it is not conclusive as it stands (see Mental causation §3).

3 MI and the computational theory of vision

One branch of psychology has been the focus of particular attention by philosophers discussing MI. This is the computational theory of vision, developed by David Marr (1982) and others (see Vision §4). The theory has received much attention because it is among the most developed areas of cognitive science. This makes it possible to look in detail at the actual practice and methodology of a psychological theory and give substance to the debates about the individuation of psychological states.

Tyler Burge (1982; 1986) argues that the theory has an anti-individualist methodology. He argues that the theory assumes that the human visual system has evolved to be successful on earth, and certain of the earthly environmental conditions that account for its success are relevant to the individuation of its representational states. Roughly, Burge's idea is that the content of certain representations is partly determined by what 'normally' cause them, where the 'normal' cause of a type of representation is the type of external condition that has caused it in the past, during the (phylogenetic) evolution of the system, under circumstances where it has been successful.

The argument proceeds by stating that one could envisage alternative possible circumstances in which intrinsically identical visual systems had evolved, but in which the 'normal' causes of some of the representations were different. In such a case, the representational contents, as attributed by the theory, would have been different from what they actually are. Hence MI is violated.

The situation Burge envisages can be schematically represented. On earth (E), the 'normal' cause of a particular physical type, *T*, of representation in the visual system is *N*. Thus *T*s on E represent *N*. In a possible counterfactual circumstance, *C*, the prevailing conditions differ, but the visual system is intrinsically the same. In *C*, the 'normal' cause of *T* is *W*, where *W* is different from *N*. For example, *N* might be small, thin cracks and *W* might be small, thin shadows. When a visual system produces a representation of type *T* on E, it represents the presence of an *N* (its content being something like 'There is a small, thin crack'). When an intrinsically identical visual system in *C* produces a *T*, it represents the presence of a *W* (its content being something like 'There is a small, thin shadow').

Burge's argument is defended by a study of the theory of vision. However, it may be questioned on at least two grounds. First, it can be questioned whether the theory really accords such a crucial role to evolutionary considerations in its attributions of content. While it is true that Marr invokes evolutionary considerations at various points, it is far from clear that these considerations enter into the individuation of the contents of visual states in the decisive way that Burge claims (see Segal 1989). Second, even if the premises of the argument are granted, its validity can be questioned.

One way to question the validity of the argument involves considering in more detail the behaviour of twin subjects when they undergo a *T*. Let us consider two cases.

Case 1. *N*s are circles and *W*s are squares: these are the 'normal' causes of *T*s on E and *C*, respectively. We can suppose that light bends in strange ways in *C*, so that squares there cause the same sorts of retinal images as circles do on E. Suppose we ask subjects who are undergoing a *T* to use their hands to trace in the air the shape they

perceive. Since the subjects in the two environments are twins, they will make the same movements. If they trace a circle, this will indicate that *C* subjects are misperceiving squares as circles. *Mutatis mutandis* if they trace a square. Thus the twins would appear to be undergoing representations with the same content after all.

This first case brings out the point that vision must be successful in both environments, if Burge's argument is to work. The second case brings out a consequence of this point.

Case 2. Suppose that *W*s are thin shadows and *N*s are thin cracks. If the success constraint is to be met, then the subjects must not behave as if they are visually representing the items specifically as cracks or as shadows. If they did, then the behaviour in at least one environment would be inappropriate, and the constraint would be violated. If the constraint is to be met, the behaviour must be indiscriminately appropriate to either shadows or cracks. And this would suggest that the visual representations are not specific to either but represent the items in some more general way. They would represent them as a feature of surfaces that could be either a shadow or a crack: a thin, dark line perhaps.

The second case undermines the validity of Burge's argument, since it allows the premises to remain in place but negates the conclusion. If *T*s represent thin, dark lines in both environments, then it may remain true that the visual systems are successfully adapted and *T* type representations represent their 'normal' causes. For thin cracks and thin shadows are all instances of thin, dark lines. This point can be generalized to the schematic version of Burge's envisaged situation: *T*s do not represent *N*s or *W*s specifically as *N*s or as *W*s, but rather represent them by some more general content, *G*, where *G* includes both *N*s and *W*s. (The objection is given in Segal (1989), and related points are made by McGinn (1989) and Matthews (1988). For extensive discussion, see Egan (1991; 1992), Davies (1991), Wilson (1994) and Segal (1991).)

The debate between methodological individualists and their opponents remains unresolved. This is because the arguments are complete on neither side, both in the particular case of vision, which has been studied in detail, and in the more general, but more complex, case of psychology as a whole. Anti-individualists have tended to rest their positions on arguments the premises and validity of which may easily be doubted, or on general theories of content that are themselves highly controversial. On the other hand, no convincing considerations in favour of a generalized methodological individualism have yet been offered.

Mexico, philosophy in

Philosophy has been practised in Mexico for centuries, beginning with Nahuatl thought. Such thinking was rediscovered through laborious translation of surviving fragments of a document of exceptional value known as ‘Coloquio de los Doce’ (Debate of the Twelve) *(1524). Since then, philosophy has come to enjoy a high degree of professionalization and a high quality of academic production. Generally, Mexican philosophical activity has evolved in accordance with world standards of rigour, information and quality of argumentation. In the twentieth century various philosophical groups have been created, namely the Ateneo de la Juventud, the* contemporáneos *and the Hyperion group.*

Leopoldo Zea understood the essence of the Mexican and the Latin American as a historical being with a historically situated consciousness. Zea's history of ideas involved a philosophy of Latin American history which placed the being, destiny and meaning of the history of Mexico and Latin America in the context of the history of the world. The 1940s and 1950s were unusually productive to this end. In the 1970s small groupings of philosophers gathered to focus on problems, traditions, teaching figures, leaders and spheres of influence.

There has been considerable interest in political philosophy, philosophy of history, philosophy of science and ethics. Since the 1980s, works about the history of ideas in Mexico and the history of science and technology have proliferated.

1 Historical overview

Before the arrival of the Europeans, a form of reflection was developed in Nahuatl society which was expressed aphoristically and poetically. Since the 1950s Nahuatl thought has been rediscovered through laborious translation of surviving fragments. A document of exceptional value is one known as ‘Coloquio de los Doce’ (Debate of the Twelve) (1524), a relatively brief fragment located in the Vatican archives. It records the encounter of cultures and the debate sustained by the first twelve Franciscan monk preachers who arrived in New Spain to preach the Gospel. The Franciscans met with native authorities and explained the New Testament to them. The natives believed that the questions were too complex and that they required the intervention of wise, erudite people. Their proposition of calling on their *tlamatinime* (wise persons or philosophers) was accepted by the monks. After listening attentively, the wise Nahuas claimed that the monks appreciated the information and greatly valued the sacrifices made by these foreigners in voyaging to transmit their truths, although the natives themselves had their own truths, which they also set forth. However, the Nahuas conceded that the monks were clearly in charge and could do whatever they wished with the Nahuas anyway. ‘Coloquio de los Doce’ (Debate of the Twelve) is important as testimony of a decisive encounter between the Western world and the so-called New World. Some of the most important topics of debate since the 1980s are addressed in a singularly ceremonial and dramatic manner: the experience of alterity, ethnocentrism, intercultural dialogue and the clash of argumentative styles. These documents reveal a rational, logical, rigorous, erudite and civilized mind on the part of the Nahuas.

After the arrival of the conquistadors from Spain in the sixteenth century a philosophy initially developed in Spain and a system of philosophical production and styles in accordance with the prevailing sociopolitical system was imposed over a period of three centuries (from the early sixteenth century to the mid-nineteenth century). Early on, the Spanish felt it important to establish a university system that would follow the model of the Universities of Salamanca and Alcalá de Henares. The University of Pontificia was founded in New Spain in 1553. The hegemonic philosophical thought in New Spain was fundamentally Scholastic. It was developed in the university, schools and seminaries and was primarily disseminated by the religious orders. Among the most important representatives is Fray Alonso de la Vera Cruz, the first to teach philosophy in the New World at the University of Pontificia in 1553.

Since the early years of the colonial period, two opposing types of reflection have been observed: colonialist and independent thought, the latter of which battles for freedom of thought and action. Sor Juana Inés de la Cruz and the Mexican Jesuits, who collaborated in the formation of a native conscience, were significant proponents of this second position (see Feminist thought in Latin America). At the end of the colonial period the same Scholastics continued to consolidate the thought of the Enlightenment, even when it seemed clear that the inspirational and legitimizing thought of independence was the so-called populist doctrine of Salamanca. The doctrine held that the

people are the source of power and power should devolve to them when the King is not in a position to exercise authority, as was the case with Fernando VII.

The nineteenth century in Mexico has also been re-examined. It has been observed that thought under the rubric of liberalism is not homogeneous and requires multiple approaches. Diverse discourses have been placed in opposition to one another. Towards the end of the nineteenth century, positivism became predominant and remains one of the most debated philosophical movements in Mexican thought (see Positivist thought in Latin America).

In the twentieth century a group of philosophers called the Ateneo de la Juventud quickly launched its anti-positivist spiritualist reaction during the Mexican revolution (1910-17) (see Anti-positivist thought in Latin America). Subsequently, the Contemporáneos constituted another decisive group in the advance of Mexican thought. By the 1950s the Hyperion group had formulated a Mexican philosophy. José Vasconcelos and Antonio Caso of the Ateneo were influential in the world of philosophy, as were Samuel Ramos of the Contemporáneos and Leopoldo Zea, Luis Villoro, Emilio Uranga, Jorge Portilla and Joaquín Sánchez Macgregor of the Hyperion group.

A notable contribution to the development of modern Mexican thought was that by the exiles of the Spanish Republic who arrived in Mexico around 1939. José Gaos, Joaquín Xirau, Juan David García Bacca, José María Gallegos Rocafull, Eugenio Imaz, Eduardo Nicol and Wenceslao Roces remain exemplars of Mexican philosophical life in the late twentieth century. Philosophers of this time are disciples of this aforementioned group who were responsible for defining the philosophical task in Mexico. Each of them has reached international levels of excellence in debate, production, philosophical rigour, argumentation, technique and information.

2 The situation in the 1990s

The situation in the 1990s is not easy to delineate. It cannot be reduced to what has been produced since 1990, nor to what was produced after either the linguistic change, or the final works of the Hyperion group. Focusing on the second half of the twentieth century, it is possible to establish the state of debate and philosophical production in Mexico in the late 1990s.

The careful study of European thought, German in particular, resulted in the development of phenomenology and existentialism in Latin America. Both these schools of thought dominated the principal centre of reflection of the country in the 1950s, which was the department of philosophy and letters at the National Autonomous University of Mexico (UNAM) (see Existentialist thought in Latin America; Phenomenology in Latin America). José Gaos made the very first translation into Spanish of *Being and Time* (1943). In that environment, the efforts began of the Hyperion group, whose name was taken from J.C.F. Hölderlin to signify the joining of heaven and earth. With the tools of phenomenology and existentialism, this group attempted to cast philosophical light on the essence of being Mexican. In an effort lasting around three years, they challenged the task of philosophy in Mexico and internationally, although they did not achieve their intended goals. Emilio Uranga (1952) published his classic analysis of the essence of the Mexican, but it was soon apparent that the achievements of this ontological route were meagre. However, a historicist trend developed and has been productive since the 1950s.

The thought of Leopoldo Zea understands the essence of the Mexican and the Latin American as a historical being with a historically situated consciousness. It is feasible to study the development of that historical consciousness expressed in the history of ideas in the region. From the beginning of that labour of reconstruction derive several modes of philosophizing. In the case of Zea, that history of ideas involved a philosophy of Latin American history which would place the being, destiny and meaning of the history of Mexico and Latin America in the context of the history of the world. The 1940s and 1950s were unusually productive to this end. In the 1970s philosophical positions were well defined, consolidated and manifested in compact groupings. Each one had its own problems, traditions, teaching figures, leaders and spheres of influence.

Leopoldo Zea led the group which focused on Latin America. He emphasized the study of the position of Latin America in the world situation and advanced the history of ideas in what José Martí called ‘Our America’. The antecedents of these teachings, whose points of focus were Latin American identity incorporating a wide cultural focus, were Caso, Vasconcelos, Reyes, Henríquez Ureña, Ramos and Gaos (see Cultural identity).

Marxist reflections were headed by Eli de Gortari and Adolfo Sánchez Vázquez (see Marxist thought in Latin America). De Gortari advanced the study of dialectical logic and the relations between philosophy and the hard

sciences through his seminar on history and the philosophy of science. He also initiated the study of the history of science in Mexico. Sánchez Vázquez formulated a solid argumentation that understood Marxism principally as a philosophy of praxis and a tool for critical aesthetic reflection. Both philosophers employ up-to-date information and argumentative rigour and both have become engaged in the international Marxist debate with a critical, suggestive and stimulating slant. An explicit focus on both the Mexican and Latin American Marxist traditions would highlight the arguments of Lombardo Toledano and José Revueltas.

A third focus has been analytic thought characterized by the linguistic trend (see Analytical philosophy in Latin America). Advanced by Luis Villoro, Fernando Salmerón and Alejandro Rossi, this group incorporated into academic debate the Anglo-Saxon tradition and the classic problems of philosophy of language, mind and science. Strongly professionalized, this group aspires radically to modify philosophical tradition in the region, incorporating modalities and styles of philosophical production in common with Anglo-Saxon countries. Their centre of study is the Institute of Philosophical Research at the National Autonomous University of Mexico. They do not refer to antecedents in the region and maintain a scientific conception of philosophy.

A fourth sector is metaphysical thought, which focuses on ancient philosophy in the tradition of Eduardo Nicol and his principal disciple Juliana González. A preoccupation with the philological and an emphasis on genetic studies in an articulation of aesthetics, ethics and gnoseology mark their thought patterns.

This cartographic outline seemed immutable in those years. Nevertheless, by the end of the 1970s modification of the agenda in Mexico had begun. New generations developed new themes; the trauma of 1968 with its consequences on academic life, along with new social demands and changes in the world began to split this four-part schema, although derivations of their philosophies are still in evidence. The critical reception of L.P. Althusser, political philosophy, epistemology, history, ethics and aesthetics were pushed to the foreground. During the 1980s decisive transformations were produced in contemporary Mexican life and changes at world level affected philosophical reflection which, with few exceptions, was maintained in cloistered areas from an endogenous academic viewpoint. Debates regarding structuralism, Marxism, semiotics and discourse theory; the production of knowledge, liberation, modernism; deconstruction and postmodernism tangentially traversed traditional boundaries which were previously impenetrable.

The philosophical positions developed throughout the 1970s and 1980s have not become outmoded, although they have crossfertilized to a degree and the forum for argumentation and frank debate has expanded. Philosophical activity has expanded outside of the institutions in which it was once confined, namely the department of philosophy and letters and the Institute of Philosophical Research at the UNAM. High-quality work has been carried out at the Autonomous Metropolitan University, especially the Iztapalapa and Xochimilco campuses, at the Jesuit Iberoamerican University, the Intercontinental University and the universities of Chihuahua, Toluca, Guadalajara, Xalapa and Ciudad Juárez.

The topics and areas of study have become richer and more varied. The history of ideas has been pursued with increased interest. There are as many works about Pre-Columbian thought in the Nahuatl field as in the Mayan, as well as in the area of recent indigenous thought, particularly that of the Huicholes. The colonial period is under exploration in an effort to refute its dismissal by positivist historiography. The development of philosophy in the nineteenth and twentieth centuries is under discussion. Monographic studies emphasize access to and retrieval of source material. All this historiographic work has brought advances in the debate over methodological and epistemological questions.

In the 1990s the precarious state of the history of science and technology in Mexico changed markedly. Rescue of sources, new methodological foci and the correlation of local with world history have facilitated work on the relationship between the history of science and ideas. In the area of the philosophy of science, work on the theory of argumentation, scientific language, models of justification and the links between hard sciences and social sciences have been produced. In political philosophy, work has been undertaken related to the idea of democracy, its processes of democratization, its manifestations of power, civil-state relations, mass communications and their prevalence in everyday life, national identity and ethnic and/or regional identities. Feminist thought has grown and developed widely in Mexico. Discussions about gender, ways of knowing and the role of women in the history of philosophy are of particular interest. Also, studies in the philosophy of law, human rights, minority rights and critical criminology have been produced. In the area of ethics, studies have come about stimulated by the

deterioration of living conditions for the vast majority and the need to clarify the rules of social life. Debates regarding historical knowledge, historiographic methodology, the role and meaning of Mexico in the world, the discourses that make up the course of history, have arisen within the sphere of the philosophy of history. There has been an important effort to establish a hermeneutics of Mexican and Latin American culture which surpasses the traditional framework of philosophy of culture and incorporates the study of popular traditions.

Among the established philosophical journals in this area are *Cuadernos Americanos*, *Cr ítica*, *Dialéctica* and *Estudios*. The most active organizations in the promotion of philosophical activities have been the Asociación Filosófica de México (Mexican Philosophical Association), active for twenty-five years and counts among its members the most important and productive philosophers of the country, the Asociación Filosófica Feminista de México (Mexican Feminist Philosophical Association) and the Círculo Mexicano de Profesores de Filosofía (Mexican Circle of Professors of Philosophy).

There have also been numerous academic events in the Mexican philosophical agenda, such as the congresses of the Mexican Philosophical Association, the Mexican Circle of Professors of Philosophy, the Mexican Society for the History of Science and Technology and those dedicated to the study of philosophy in New Spain. The ninth Interamerican Congress of Philosophy took place in Guadalajara in 1985 and the first International Congress of Latin American Philosophy took place in Ciudad Juárez in 1991.

It is worthy of note that philosophy is still taught at the secondary level in Mexico. There is considerable interest in improving the quality of the teaching of philosophy to prepare students for life and future university studies.

3 Prospects

Despite the financial crisis and the budget restrictions that chronically affect Mexican academic institutions, the future of the philosophical agenda in Mexico is promising. Young people with excellent training are slowly becoming involved in philosophical production and other institutional frameworks are surfacing to support philosophy such as the professional associations. The growing social and cultural problems demand inclusion in the philosophical agenda. With a population subject to inhumane deficiencies and with the increase in poverty in real and absolute terms, philosophy is called upon to attempt adequate responses. Also, the process of democratization in the country is demanding philosophical contributions. Cultural creativity continues at its highest level and demands adequate aesthetic reflections which address the phenomenon. Globalization demands new conceptualizations which help address intellectual perplexity.

Meyerson, Émile (1859-1933)

Meyerson rejects the positivism of Comte and Mach, insisting that reason demands more of science than the identification of lawful regularities for the purpose of successful prediction. Reason demands an actual representation of reality based on genuine causal explanation, and causal explanation consists of demonstrating an underlying identity behind the apparent diversity of phenomena. If completely successful, however, such explanation would ultimately lead to the unchanging homogeneous and sterile universe of Parmenides. That it does not is due to what Meyerson calls 'irrationals': inexplicable elements in reality that can never be reduced to identity. Explanation, therefore, is never complete, and scientific laws are 'plausible' rather than universally and necessarily true.

Émile Meyerson was Polish by birth but French by choice. In 1882, after studies in Germany under the celebrated chemist R.W. Bunsen, he began his career in the inorganic chemistry laboratory at the Collège de France. Abandoning chemistry in 1889, he served as a foreign policy editor for the Havas News Agency, then turned to philanthropic work with Jewish emigrants to Palestine, eventually becoming director for Europe and Asia Minor of the Jewish Colonization Association.

Meyerson's erudition was legendary. Although he never held an academic post, he was enthusiastically accepted by the French intellectual community, and his office was a gathering point for eminent philosophers and scientists. When he wrote about the history of science, he had usually read the primary material in the original language. When he wrote about contemporary science, he had often discussed it personally with the scientists who created it.

Although often classified as an epistemologist and/or philosopher of science, Meyerson himself describes his work more broadly as 'philosophy of the intellect' (from 'Philosophie de la nature et philosophie de l'intellect' in 1936), which he differentiates both from logic, because he is concerned with how we actually think rather than how we ought to think, and from psychology, because he is concerned not with direct introspection, but with analysis of the products of thought in order to discover a posteriori the a priori component of our thought processes. On the basis of exhaustive concrete examples, especially from the history of science, but also from the history of philosophy and ordinary common sense reasoning, he identifies an a priori tendency in all reasoning to replace diversity in appearances with identity in reality.

To explain (*expliquer*) an event is to explicate (literally, to unfold) it from its cause to show that it already existed in the cause, and is in this sense identical with it (1921: 9) (see Causation; Explanation). In scientific reasoning, the example *par excellence* of this identity is conservation laws, which maintain that throughout changing appearances the underlying amount of mass, energy, inertia, and so on, remains constant, that is, identical (Zahar 1980) (see Conservation principles). Such laws are both analytic and synthetic: analytic in so far as they exemplify the innate tendency to establish real identity behind apparent diversity, but synthetic in so far as what specifically is posited as identical, for example, momentum, is determined empirically. Meyerson classifies such laws as 'plausible' (1921: 410). This word is to be understood in a strong sense, for, because of their a priori basis, laws have an element of true necessity. But, because of their empirical content, this plausibility falls short of strict necessity.

Other scientific examples abound, such as the persistence of the same chemical elements in the raw material for a chemical reaction and its product, or the permanence of physical atoms throughout physical change, which allows us to explain the diversity of secondary qualities in terms of changes in position in homogeneous space of unchanging material particles. But the a priori tendency toward identity is not confined to formal science. Common sense also seeks to replace the diversity of experience with an underlying permanent reality. For example, we posit the existence of a real table that remains identical in spite of our changing, diverse sensations of the table, and we form the concept of table by ignoring the differences among individual tables and identifying a common (identical) essence.

The identification is never complete, however, whether in scientific or common sense reasoning; at some point we are inevitably confronted with brute diversity which cannot be reasoned away, that is, with one or more

'irrationals' (1908). Perceptual diversity remains even as we reduce the table to its defining geometrical elements, and salt clearly differs from sodium plus chlorine even after we have explained that it is simply sodium chloride. For Meyerson the example *par excellence* of such irrationals is the second law of thermodynamics, and Carnot has the place of honour in Meyerson's scientific pantheon. If there actually were a strict identity between cause and effect, then all physical processes would be reversible. But entropy necessarily increases; there are irreversible processes; identity of cause and effect is not complete (see Thermodynamics). Quantum mechanics, with its indeterminacy principle, presents us with a startling new example of an intractable irrational in physical explanation (see Heisenberg, W.; Quantum mechanics, interpretation of §2), but classical mechanics provides examples as well. Even if the classical mechanist were to succeed in reducing all causal explanation to the physical impact of elementary particles, for example, the causal mechanism of the impact itself - how force or momentum is passed from one particle to another - would continue to defy analysis.

Although a scientific realist, Meyerson insists that his concern is not with metaphysics but only with the philosophy of the intellect. There must be a partial correspondence between our rational theories of reality and reality itself or the success of scientific inquiry could not be explained, but it is the a priori tendencies in our thought processes rather than the nature of physical reality in which he is interested. The correspondence between the structure of our thought and the structure of reality, though necessary, is not complete. Reality is also recalcitrant to our reasoning processes. We are inevitably confronted with irrationals, and there is no way of predicting when they will arise or in what form. We face an epistemological paradox (1921): reason demands identity, but even a Cartesian or Einsteinian world in which matter is reduced to the geometry of space fails to acheive complete identity; nothing less than the sterility of absolute Parmenidean homogeneity will do. Our reasoning is successful only in so far as it does establish identity, but its explanatory power depends also upon its ultimate failure. We succeed in explaining diversity by finding underlying identities while admitting that, nevertheless, there really is change and diversity, which, in the end, we cannot fully explain. Genuine explanation is possible only because the irrational cannot be completely eliminated.

Mi bskyod rdo rje (1507-54)

Mi bskyod rdo rje (Mikyö Dorje) was a Tibetan Buddhist of the Karma bKa'-brgyud (Gagyü) school. Particularly in his earlier thought, he defended the existence of a positive nondual Ultimate Reality (an Absolute) beyond all conceptuality but known in meditation, and apparently understood the purpose of Mādhyamika philosophy as solely the shattering of conceptualization and all philosophical positions as a preparation for this nonconceptual meditation. He was highly critical of Tsong kha pa (Dzongkaba, a notable philosopher of the rival dGe-lugs-pa (Gelukba) school), for being overly concerned with logical analysis of the foundations of everyday experience.

Mi bskyod rdo rje (Mikyö Dorje) was the Eighth Karma pa hierarch of the Karma bKa'-brgyud (Gagyü) school of Tibetan Buddhism. He was born in Damchu (East Tibet) and died of leprosy at Dakpo Shedrup Ling Monastery (East-Central Tibet). The bKa'-brgyud tradition inherited from its Indo-Tibetan yogic origins a dislike of philosophy and logic, which was seen as an over-concern with conceptuality. Emphasis was placed on direct experiential knowing, associated with a meditation system known as *mahāmudrā* ('the Great Seal'). *Mahāmudrā* is said to involve the immediate experience of one's own mind, which is actually the primordial self-luminous empty mirror-like wisdom-Mind of Buddhahood. All things are the spontaneous unobstructed play of this fundamental Mind, which is held to be the primordial Reality beyond all conceptuality and linguistic distortion. The direction of bKa'-brgyud thought is primarily towards moulding a sufficient theoretical framework for this *mahāmudrā* meditation. Nevertheless, Mi bskyod rdo rje devoted impressive intellectual effort to establishing the philosophical position of his school, furnishing the Karma bKa'-brgyud tradition with its own commentaries on some of the principal works used in the Indo-Tibetan monastic curriculum.

At the time of his full ordination as a monk, Mi bskyod rdo rje was exhorted to promulgate 'the view of other-empty' (*gzhan stong*) (see Tibetan philosophy §1). This involves the existence of a true Ultimate Reality, empty of what is other than it in that it is essentially empty of whatever is non-Ultimate, but nevertheless an Absolute, an Ultimate Reality having itself all the intrinsic qualities of Buddhahood. This 'other-empty' position contrasts with a view held within Tibetan Buddhism notably by the dGe-lugs-pa (Geluk) tradition that all things without exception are empty of their own inherent existence (*rang stong*) and exist only relatively. There is no Ultimate Reality at all, as an actual Absolute. There is some suggestion that even at the early age of 23 Mi bskyod rdo rje wished to adopt an other-empty approach in a combative commentary he wrote on the Perfection of Wisdom (*Prajñāpāramitā*) scriptures. At about the same time he also wrote a short independent work on the other-empty perspective. In it he speaks of the other-empty view as that of the Great Madhyamaka. He traces it to Maitreya, Asaōga and Vasubandhu, but he wants to distinguish this Great Madhyamaka view from the 'Mind-only' (*cittamātra*) vision often associated with those figures, which for Mi bskyod rdo rje seeks to establish the flow of relative, tainted ('everyday') consciousness as the Reality (see Buddhism, Yogācāra school of §§1-4, 8). Mi bskyod rdo rje sees the Great Madhyamaka as also the final perspective of Nāgārjuna. He is, however, very critical of certain 'pseudo-Mādhyamikas' (including apparently the renowned scholars Candrakīrti and Haribhadra) for whom there is no Ultimate Reality, and the ultimate truth is itself simply an emptiness of inherent existence (that is, the *rang stong* perspective). Such an emptiness is a mere negation, and could not be the Ultimate referred to in Mahāyāna Buddhist sources, an Ultimate which, as nonconceptual, is realized in direct yogic experience and is not accessible to the negations of logicians like Candrakīrti. The rival view that would make the ultimate *qua* Ultimate Reality nonexistent is a form of nihilism. By way of contrast with the Ultimate Reality, for Mi bskyod rdo rje in reality all conventional, relative, mistaken appearances simply do not exist, and are not known even by the Buddha's omniscience.

However, In Mi bskyod rdo rje's commentary on Candrakīrti's *Madhyamakāvatāra (Supplement to the Middle Way)*, written many years later, he criticizes a number of important Tibetan figures associated with the other-empty tradition, and interprets Candrakīrti's text in a 'self-empty' (*rang stong*) manner. It has been suggested (Ruegg 1988) that this could be seen as Mi bskyod rdo rje's response to dGe-lugs criticisms. On the other hand, since he makes no mention in interpreting the *Madhyamakāvatāra* of any major other-emptiness lineage of interpretation, and given his criticisms of Candrakīrti in his previous work, it seems possible that Mi bskyod rdo rje wished to show that Candrakīrti (or conceptualized Madhyamaka) could only be interpreted in a self-empty and not an other-empty manner. In this commentary Mi bskyod rdo rje shows his impatience with those

who see Candrakīrti as a system-builder. Candrakīrti’s intention is simply absence of delusion, through demolishing all conceptual philosophical systems. We are left with nothing as far as conceptual philosophizing goes, and even terms like ‘emptiness’ are simply conceptual devices to be used pedogogically. Things having thus been cleared away, Mi bskyod rdo rje holds that we should now engage in direct yogic experience through *mahāmudrā*. Although even someone who follows Madhyamaka will continue with the pre-reflective activities of the ‘person in the street’, there can be no satisfactory systematically coherent and rational philosophical foundation for those activities. Mi bskyod rdo rje is particularly critical of Tsong kha pa Blo bzang grags pa (Dzongkaba Losang dragba, 1357-1419) and the dGe-lugs tradition here. Tsong kha pa’s view, as represented by Mi bskyod rdo rje, is that emptiness is the essence of things, *qua* their lack of their own inherent existence. Thus there is a level on which things are coherently founded, in order for them to be empty. Nevertheless *all* things are empty, including emptiness itself. So Tsong kha pa thinks that things can be rationally *shown* to have *an* existential status, although there is no Ultimate Reality at all. For Mi bskyod rdo rje, in the face of any critical analytic investigation nothing can be founded, and it is unseemly to be so concerned with founding the relative and mundane conventional. Also, he says, Tsong kha pa’s emptiness is itself just a ‘limited emptiness’ (*itaretaraśūnyatā*), the relative, mundane emptiness that we see in the everyday context of two different things where ‘*x* is empty of *y*’. Tsong kha pa’s emptiness could not be the Ultimate, the emptiness which could serve as a true basis for the path to liberation.

Not particularly technical.)

Midrash

Midrash, a Hebrew word meaning 'investigation' or 'study', denotes both the method used by the Jewish rabbis of the second to sixth centuries AD *to interpret the Bible and the extensive literature that resulted from the application of that method. In rabbinic parlance midrash, or the related term derash, can also designate a homiletic, non-literal way of reading the Bible. Midrash embodies a distinctive hermeneutic which at its most extreme treats the text of Scripture as a set of symbols or signs apparently to be manipulated by the interpreter at will. In recent years midrash has been compared to reader-response literary criticism. It has also been claimed that it represents a 'Judaic' as opposed to a 'Hellenic' mode of thinking which anticipates postmodernist hermeneutics.*

1 Midrash as literature

The extensive midrashic literature falls into two broad types: exegetical midrashim, which comment more or less verse by verse on a biblical book (for example, *Bereshit Rabba* on Genesis), and homiletic midrashim which comment on the Scriptural readings for a series of festivals or special days of the liturgical year (for example, *Pesiqta de-Rav Kahana*). These texts are constructed out of small units of discourse which employ a limited number of highly patterned literary forms. These basic forms are organized into higher forms, larger units of discourse which make a single theological, homiletic, or legal point. The higher forms are then collected into documents or composite forms which usually have some sort of overarching programme. Thus the basic forms of a midrash (in the sense of a single exegetical operation), a *mashal* (parable) and a dictum may be combined into the higher form of a homily, and a number of homilies may in turn be combined into a composite form such the document known as *Pesiqta de-Rav Kahana*. The various documents are closely related to each other and share material. Later stages of the tradition often seem to be developing or reacting to earlier ones. The contents of the documents differ from manuscript to manuscript; and they are not authored texts in any strong sense of that term, but neither are they random collections. They are an evolving literary canon which holds the deposit of the teaching and preaching on the Bible in the rabbinic academies and the synagogues of Palestine in the second to sixth centuries AD.

2 The hermeneutic methods of midrash

In midrash, the Bible is seen as a unique text which originated in the mind of God. The contribution of its human authors is discounted. They wrote under the influence of a divine power ('the holy spirit') which neutralized their human failings and ensured that they transmitted accurately the divine message. The text is fixed, unalterable and authoritative for all time. It is completely consistent and can contain no errors of fact, nor any contradictions. When seeming contradictions appear they are harmonized. The possibility that earlier laws may have been abrogated by later laws is not admitted. All truth that is relevant to human knowledge and action is latent in Scripture and can be discovered therein if the text is investigated in the proper way. The potential of Scripture is maximized. Its text is polyvalent and can have a multiplicity of meanings. It is not seen as a problem if these contradict each other, provided they are properly derived, since it is assumed that the contradiction is resolved in the mind of God. The text of Scripture contains no redundancy. If the same statement is found in two places its meaning will be differentiated: for example, in one place it will be referred to the present age, in the other to 'the age to come' (that is, the Messianic age).

Seen from outside the tradition, the function of midrash is twofold: (a) to apply the fixed text of Scripture to changing historical circumstances; and (b) to validate post-biblical practices, institutions, ideas and laws from the Bible. From within the tradition this second function is rarely openly acknowledged. It is normally assumed that the exegete is drawing out meaning objectively contained within Scripture and not subjectively reading meaning into it. Various techniques are used to explicate or extract meaning from Scripture, some of them manipulative in the extreme. For example, in the device known as *gematria* meaning can be derived by computing the numerical value of the letters. Several lists of the hermeneutical rules (known as Middot) used in midrash are extant. But these listings by no means exhaust the techniques of midrash. Despite the appearances, midrash is a disciplined activity: there must be some objective 'peg' in the biblical text (for example, a lacuna in the narrative, or an unusual linguistic usage) on which to hang the interpretation.

The manipulative approach to the reading of Scripture created an obvious problem of authority, since it would also

allow heretical (for example, Christian) views to be validated from Scripture. This problem was addressed in a number of ways. It was asserted that, whatever midrashic meanings were derived from Scripture, the text could never lose its simple or literal (*peshat*) sense. It was also claimed that the correct interpretation of Scripture could be given only by those who had studied in the rabbinic academies with approved teachers who stood in an unbroken tradition of teaching going back to Moses. The tradition of commentary was elevated to the status of Scripture. It was designated oral Torah in contrast to the written Torah (the Scriptures), and its origins were traced back to Sinai, the supreme moment of revelation when the written Torah was given to Israel.

3 Midrash as a 'Judaic' mode of thinking

The term 'midrash' has passed into contemporary academic discourse, because certain literary critics have suggested that midrash anticipates postmodernist ways of reading texts. They note with approval that midrash often behaves with remarkable freedom towards the text, offering a strong reading, which may at times stand the plain sense on its head. They compare the midrashic postulate that Scripture has a multiplicity of meanings to the postmodern claim that a text does not have a single absolute and objective sense, that its meaning varies from reader to reader and that no one reading can be privileged as more correct than another. Some go further and suggest that midrash embodies a distinctively 'Judaic' mode of thinking which is semiological, auditory and algebraic, in contrast to the ontological, visual and geometrical 'Hellenic' mode of thinking that has dominated Western hermeneutics in modern times.

These claims are historically questionable. The methods of midrash may superficially resemble postmodern literary criticism, but there are important differences. The rabbis regard midrash as an activity that relates to one unique text alone, the Bible. They do not see it as a paradigm of how to read every text. Moreover, they believe that Scripture does have an objective and absolute meaning, although in its entirety this is known only to God. Their mode of interpretation is disciplined, not arbitrary. By the application of the correct procedures the duly accredited and responsible rabbinid exegetes could draw out hidden senses from Scripture, but these senses were all facets of a larger and deeper, *objective* truth. The rabbinic exegetes could no more exhaust the potential of the text than they could exhaustively know the mind of God. But the inexhaustibility of their readings was taken not as a badge of their own creativity but as the emblem of the richness of the text itself. The polarization of Judaic and Hellenic hermeneutics, moreover, ignores the fact that many of the midrashic techniques are found applied to the interpretation of texts in Greek late antiquity.

Mikhailovskii, Nikolai Konstantinovich (1842-1904)

Along with Lavrov, N.K. Mikhailovskii, a non-academic social theorist and literary critic, was the most representative and influential thinker of Russian populism. His most distinctive contribution to populist ideology was his attempt to reconcile the 'principle of individuality', so dear to the Russian intelligentsia, with the old, communal 'principles of the people', represented by the non-Westernized Russian peasantry. Unlike Herzen and Lavrov, Mikhailovskii did not see the principle of individuality as a product of Western progress, that is to say, as something which should be introduced from outside to the archaic world of Russian village commune. He challenged the stereotype which associated individualism with the capitalist West; instead, he tried to prove that the principle of individuality was in fact fully compatible with old Russian communalism, and incompatible with Western-type modernization. He did so by a radical redefinition of the very concept of individuality. For him individuality was not the product of a process of 'individualization' in the sense of loosening the communal bonds, making people socially differentiated, functionally specialized and separated from each other. On the contrary, by individuality he meant the 'inner wholeness', that is to say, the non-alienated, many-sided and harmonious development of human beings. Following the romantic critics of modernity, he claimed that individuality, so conceived, was being destroyed by capitalist progress.

Mikhailovskii's notion of individuality was similar to the Slavophile ideal of 'integral personality'. Unlike Slavophilism, however, Mikhailovskii's 'sociological romanticism' was bound up with a secularist worldview and a semi-positivist position in philosophy. For this reason its affinity with Slavophile romantic anticapitalism was relatively inconsequential and remained unnoticed.

1 Anthropological relativism and ethical personalism

Mikhailovskii admired the Russian word for truth - *pravda* - as designating not only theoretical truth but also truth as justice, truth of the moral consciousness. In his view the common root of the two sides of truth was provided by the principle of individuality, treating the concrete human individual as the measure of all things.

The application of this principle to epistemology led to a relativist, or 'subjectivist', theory of knowledge. Absolute truth, or truth in itself, cannot exist; there is only truth for man and, in addition, it is not the same for the entire human species. Concrete truth is always perspectivist; the so-called facts are not something objectively given, their perception and interpretation is preformed by the nature of our social bonds, the type of social cooperation and, last but not least, by the irreducible individual experience of each human being. Hence there is no escape from subjectivism in theoretical knowledge: 'truth is that which satisfies the mental cravings of man'.

However, this epistemological relativism was combined by Mikhailovskii with an unyielding ethicism, treating the human individual as the central and absolute value. For Mikhailovskii this axiological absolutism was simply the other side of his view that the individual was the only basis of truth. If this is so, he reasoned, human knowledge is always relative, but in the realm of values all humans should accept the principle of individuality as the absolute standard for truth as justice. The individual, he argued, is sacred and must never be sacrificed. The individual's need for wholeness was for him a universal phenomenon; therefore the wholeness of individual human beings was in his view the absolute criterion in axiology. Thus, his 'subjective sociology' was based on two tenets: extreme epistemological relativism, often taking the form of a sociological theory of knowledge, and ethical absolutism, elevating the value of the all-round human personality.

2 Theory of progress

The application of Mikhailovskii's axiology to social sciences led to a reversal of the liberal view of progress, as expressed, in particular, in Herbert Spencer's positivistic evolutionism (see Spencer, H.).

In his treatise 'Chto takoe progress' ('What is Progress?') (l869) Mikhailovskii accused Spencer of overlooking the fact that individual progress and social evolution (on the model of organic evolution) were mutually exclusive. Spencer defined progress in the organic world as transition from simplicity (homogeneity) to complexity (heterogeneity); in society the same organic evolution was being achieved through the development of the division of labour. The Russian thinker set against this theory a sociological conception which claimed that the development of the division of labour in society was essentially a retrogression, since it had been achieved at the

expense of individuality, which had suffered fragmentation and disintegration. This was so because only in an undifferentiated, egalitarian society can human individuality be diversified, integral and well-rounded. True progress, Mikhailovskii concluded, ’is the gradual approach to the fullest possible and the most diversified division of labour among man’s organs and the least possible division of labour among men’.

In his other works, especially in the series of articles ’Bor’ba za individualnost’’ (’The Struggle for Individuality’) (1875-6), Mikhailovskii used this formula as an argument for a backward-looking peasant utopia, idealizing the natural economy of the Russian village commune. The Russian peasant, he argued, lived a life that was primitive but full; he was economically self-sufficient, and therefore independent, many-sided, making use of all his capacities, being a tiller and a fisherman, a shepherd and an artist in one person. The absence of complex cooperation made the Russian peasants mutually independent, while simple cooperation (that is, a cooperation in which people were involved as ’whole beings’) united them in a moral solidarity based upon mutual sympathy and understanding. One should distinguish between *levels* and *types* of development. The peasant commune represented a lower level of development than the capitalist factory but was superior to it as a type of development; similarly, Western man belonged to a lower type of development than the Russian peasant, who had not yet lost his primitive ’wholeness’. Hence it was groundless to believe that capitalism had liberated the individual; on the contrary, it turned the individual into a ’mere organ’ of the social organism, mercilessly sacrificing concrete living individuals to the idol of ’maximum production’.

3 The struggle for individuality

Despite his criticism of biological ’organicism’ in sociology, Mikhailovskii yielded to it in his own theory of the ’struggle for individuality’. He attributed to complex societies a tendency to develop into a kind of superorganism whose human members would be reduced to the role of submissive organs. However, he challenged the Darwinian trust in the survival of the fittest with the pessimistic view that ’natural evolution’ was accomplished at the cost of a constant lowering of quality and deserved therefore to be seen as a retrograde process.

Mikhailovskii’s theory was founded on the proposition that there are different stages of individuality that struggle against each other and try to dominate each other. This proposition, derived from Haeckel’s classification of biological organisms (see Haeckel, E.H.), assumed the presence of an inevitable conflict between individual human beings and different supraindividual entities - such as factories (as units of complex cooperation), estates, nations, states and so on. All these *social* individualities could only develop at the expense of man’s freedom and wholeness. Therefore, Mikhailovskii concluded, ’society is man’s chief and worst enemy, an enemy against whom he must always be on guard’.

In his philosophy of history Mikhailovskii combined the theory of the struggle for individuality with Comte’s conception of the phases of intellectual development (see Comte, A.). He divided history into three great periods: the ’objectively anthropocentric’ period, the ’eccentric’ period, and the ’subjectively anthropocentric’ period. The first period knew only simple cooperation and could therefore preserve the original fullness of human beings. The second one, bound up with the social division of labour, was the period of development through alienation, separating the faculties of the species, objectifying them and setting against each other. The third period, which was to be realized as a result of a socialist transformation, would overcome the extreme forms of dependence on the division of labour, liberate individuals from the rule of objectified economic mechanisms and enable them to cooperate with each other in a free, ethical community.

An interesting part of Mikhailovskii’s social philosophy was his view on the question of gender. He thought that sexual differentiation of human beings had been greatly increased as a result of the extreme division of social roles and interpreted love as striving for reintegration through compensatory self-fulfilment in another being. It followed from this that in the homogeneously egalitarian society of the future the differences between sexes would be greatly reduced and the need for love much less important.

4 Mikhailovskii and Marxism

Among the authors who influenced Mikhailovskii’s view on capitalism - the highest phase of the ’eccentric’ period of history - the most important was Marx. As early as 1869, in his article ’Teoriia Darvina i obshchestvennaia nauka’ (’The Theory of Darwin and the Social Sciences’), Mikhailovskii expressed solidarity with Marx’s views

on the negative effects of the division of labour; he referred also to Adam Smith and Ferguson but, as a rule, quoted them after Marx's *Capital*. He was profoundly impressed by Marx's account of capitalist development as necessarily involving the expropriation of the immediate producers. Like other populists, he concluded from this that his country should do its best to avoid the capitalist way. Moreover, the adaptation of Marxism to his own conception persuaded Mikhailovskii that modern socialism and 'medieval forms of production', as represented by the village commune, were but different levels of the same type and, hence, that the workers' cause in Russia was essentially a conservative cause. In his review of the Russian translation of *Capital* (1872) he supported this conclusion by wholeheartedly endorsing Marx's denunciations of the class nature of 'bourgeois democracy'.

A few years later, however, Mikhailovskii became aware that Marxism contained also the notion of 'objective laws of history' and, therefore, could be used as an argument for the necessity of capitalist development in Russia. In his article 'Karl Marks pered sudom g. Zhukovskogo' ('Karl Marx Arraigned Before Mr Zhukovskii'), published in *Otechestvennye zapiski (Notes of the Fatherland)*, 1877, he reacted to this by formulating the dramatic dilemma of the Russian disciples of Marx, who as socialists saw capitalism as morally unacceptable but as historical determinists had to accept 'the capitalist phase', with all its painful consequences for the masses. Marx himself tried to dispute this diagnosis in his 'Pis'mo v redaktsiu *Otechestvennikh zapisok*' ('Letter to the Editor of *Otechestvennye zapiski*') (written 1877, published 1886) but failed to convince his Russian followers. Both Georgii Plekhanov and Pëtr Struve, the leader of the so-called 'legal Marxists' of the l890s, interpreted historical materialism as a rigidly deterministic theory, treating the capitalist development of backward countries as a historical inevitability. This caused Mikhailovskii to launch an energetic campaign against Marxism. He attacked Marxism as an 'inverted Hegelianism', trying to substitute the speculative concept of historical necessity for the empirical explanation of fact and thus justifying all the cruelties of history. Mikhailovskii's arguments exercised an influence on the 'legal Marxists', especially Berdiaev, helping them to evolve in the direction of philosophical idealism.

Miki Kiyoshi (1897-1945)

A brilliant young philosopher and critic of his times, Miki Kiyoshi embodied in his life and thought Japan's tortured transition from Westernized modernity to world power. Associated with his teacher, Nishida Kitarō, he is generally regarded as representative of a Marxist turn on the Kyoto School.

As a young student, Miki chanced upon a copy of Nishida Kitarō's *Zen no kenkyū (Study of the Good)*, which turned him to the study of philosophy (see Nishida Kitarō). After studying under Nishida at Kyoto University, he spent two years in Germany, principally with Heidegger, in whose person he came to understand the post-war angst of Europe in the 1920s. He felt drawn to the optimism of thinkers such as Bergson and to the philosophical anthropology of Dilthey and Simmel. In pursuit of his own position he moved to Paris for a year where he threw himself into the works of Pascal, culminating in his maiden work, *Pasukaru ni okeru ningen no kenkyū (Pascal's Anthropology)*, which appeared in 1925.

On returning from abroad in 1924, Miki felt himself out of tune with the 'logic of place' that was occupying Nishida's attention at the time. Eager to bring his humanistic interests in line with the questions of the historical world, he turned to Marxist thought. The following year he took a post as professor at Hōsei University, and began to publish essays on historical materialism. In 1928 he was arraigned in court on charges of making an illegal contribution to the Japan Communist Party and received a suspended two-year sentence. In his own defence he insisted that he had always taken a critical stance to Marxism, which in turn earned him the derision of the Marxist establishment.

Hardened in his resolve both to systematize his own philosophical humanism and to clarify his critique of the rising militant fascism of the time, Miki set to work on a major study, *Kōzōryoku no ronri (The Logic of Structural Power)*. The serialized publication of the work (the final section of which was only published posthumously), coincided with the onset of the Sino-Japanese War. In 1938 Miki joined the controversial Shōwa Study Group where he was the chief architect of its idea of 'commonism' (*kyōdōshugi*) a curious blend of socialist, liberal, and quasi-fascist ideas which was offered as an alternative to the 'co-prosperity sphere' that the military regime was advancing as part of its 'new world order' in Asia. Miki was dismissed as a fool by leading right-wing ideologues and the study group was disbanded.

In 1943 Miki was sent as a war correspondent to the Philippines, an express punishment for his 'red' tendencies. He returned at the end of the year, only to find that almost none of his writings would be accepted for publication. In June 1945 he was arrested on a charge of disrupting public order and the powers behind his detention saw to it that he was denied amnesty at the end of the war. He died in prison.

Miki's overriding concern with philosophy's 'duty to the times' (*jimu*) made for a certain choppiness in his thought. Had he lived to write in time of peace, there is every indication he would have brought the various threads together into a unified body of thought. In what we have of his work, perhaps the most central notion is what he calls *techné* (*gijutsu*), the transformation of reality that serves as the bridge between and final judge of all human logos and pathos. Without it, the angst of the age was apt to lead only to privatized despair and a flight from reality, a tendency he saw in Heidegger. In works like *Tetsugaku nyūmon (Introduction to Philosophy)* and *Gijitsu tetsugaku (The Philosophy of Techné)*, Miki showed how industrial technology and its social problems belong to a wider phenomenon that begins in the natural world and rises all the way to intellectual disciplines and morality in 'the *techné* of the heart' in which existential anxieties are not only accepted but creatively reshaped.

Mill, James (1773-1836)

James Mill, who is today remembered mainly as Bentham's chief disciple and John Stuart Mill's father, was a British philosopher, political theorist, historian, psychologist, economist, educationist and journalist. He was also largely responsible for clarifying and systematizing Bentham's utilitarianism, for introducing a distinction between 'lower', animal pleasures and 'higher', uniquely human ones, and for organizing the small but influential band of Bentham's followers that became known as the 'philosophic radicals'. In politics, he favoured representative democracy as the only practicable system of government capable of maximizing individual and communal happiness.

A prolific author, Mill wrote five books and more than a thousand articles and reviews. The book for which he was best known during his lifetime was his three-volume *History of British India* (1818). His *Essays* (1825) on sundry subjects - including 'Government' and 'Education' - was followed by his *Elements of Political Economy* (1826), his two-volume *Analysis of the Phenomena of the Human Mind* (1829) and *A Fragment on Mackintosh* (1835).

Despite this diversity of topics, Mill's thinking is informed by a unified philosophical vision. In psychology he was an 'associationist' who held that our beliefs and behaviour are the product of pleasurable and painful associations of ideas. In ethics he was a utilitarian who held that the proper aim of human actions and practices was the promotion of human happiness (see Utilitarianism). Unlike Jeremy Bentham (see Bentham, J. §2), however, who held that 'pushpin is as good as poetry' - that is, that a pleasure is a pleasure, whatever its source - Mill believed that happiness is not synonymous with pleasure, particularly of the 'lower' or 'animal' sort. Human happiness comes from developing and using uniquely human powers - reason, logic, the love of truth and beauty - to their fullest extent. Hence his interest in education, which leads people toward the right sorts of associations: to find truth pleasurable and error painful; to delight in doing right and experience pain in doing wrong; and so on.

These themes come together in Mill's political philosophy, which is summarized succinctly in his essay on 'Government'. Government, properly structured, promotes the happiness of the whole community and its individual members. Humans not only naturally desire happiness; they seek to satisfy that desire by investing as little effort as possible in obtaining it. Labour is the means of obtaining happiness. Humans find labour painful; hence they will, if they can, live off the labour of others. But to the extent that some live off the labour of others, the latter's incentive to work is diminished, and the happiness and prosperity of the community is imperilled.

The point and purpose of government is to maximize the happiness of the whole community by minimizing the extent to which some members live off the labour of others. Mill maintains that this aim cannot be achieved in a monarchy, nor in an aristocracy, nor in a direct democracy (the last taking too much time away from labouring). The only system capable of maximizing individual and communal happiness is a representative democracy in which representatives are elected to serve short terms before returning to the ranks of the electorate. So structured, representative government gives representatives every incentive to serve the people instead of themselves.

During his lifetime James Mill was regarded as a radical in politics and philosophy. That his ideas now seem conventional or even conservative shows how the radicalism of one age can become the conservatism of another.

Mill, John Stuart (1806-73)

John Stuart Mill, Britain's major philosopher of the nineteenth century, gave formulations of his country's empiricist and liberal traditions of comparable importance to those of John Locke. He united enlightenment reason with the historical and psychological insights of romanticism. He held that all knowledge is based on experience, believed that our desires, purposes and beliefs are products of psychological laws of association, and accepted Bentham's standard of the greatest total happiness of all beings capable of happiness - the principle of 'utility'. This was Mill's enlightenment legacy; he infused it with high Romantic notions of culture and character.

In epistemology Mill's empiricism was very radical. He drew a distinction between 'verbal' and 'real' propositions similar to that which Kant made between analytic and synthetic judgments. However, unlike Kant, Mill held that not only pure mathematics but logic itself contains real propositions and inferences, and unlike Kant, he denied that any synthetic, or real, proposition is a priori. The sciences of logic and mathematics, according to Mill, propound the most general laws of nature and, like all other sciences, are in the last resort grounded inductively on experience.

We take principles of logic and mathematics to be a priori because we find it inconceivable that they should not be true. Mill acknowledged the facts which underlie our conviction, facts about unthinkability or imaginative unrepresentability, and he sought to explain these facts in associationist terms. He thought that we are justified in basing logical and mathematical claims on such facts about what is thinkable - but the justification is itself a posteriori.

What then is the nature and standing of induction? Mill held that the primitive form of induction is enumerative induction, simple generalization from experience. He did not address Hume's sceptical problem about enumerative induction. Generalization from experience is our primitive inferential practice and remains our practice when we become reflectively conscious of it - in Mill's view nothing more needs to be said or can be said. Instead he traced how enumerative induction is internally strengthened by its actual success in establishing regularities, and how it eventually gives rise to more searching methods of inductive inquiry, capable of detecting regularities where enumerative induction alone would not suffice. Thus whereas Hume raised sceptical questions about induction, Mill pushed through an empiricist analysis of deduction. He recognized as primitively legitimate only the disposition to rely on memory and the disposition to generalize from experience. The whole of science, he thought, is built from these.

In particular, he did not accept that the mere fact that a hypothesis accounts for data can ever provide a reason for thinking it true (as opposed to thinking it useful). It is always possible that a body of data may be explained equally well by more than one hypothesis. This view, that enumerative induction is the only authoritative source of general truths, was also important in his metaphysics. Accepting as he did that our knowledge of supposed objects external to consciousness consists only in the conscious states they excite in us, he concluded that external objects amount only to 'permanent possibilities of sensation'. The possibilities are 'permanent' in the sense that they can be relied on to obtain if an antecedent condition is realized. Mill was the founder of modern phenomenalism.

In ethics, Mill's governing conviction was that happiness is the sole ultimate human end. As in the case of induction, he appealed to reflective agreement, in this case of desires rather than reasoning dispositions. If happiness was not 'in theory and in practice, acknowledged to be an end, nothing could ever convince any person that it was so' (1861a: 234). But he acknowledged that we can will to do what we do not desire to do; we can act from duty, not desire. And he distinguished between desiring a thing as 'part' of our happiness and desiring it as a means to our happiness. The virtues can become a part of our happiness, and for Mill they ideally should be so. They have a natural base in our psychology on which moral education can be built. More generally, people can reach a deeper understanding of happiness through education and experience: some forms of happiness are inherently preferred as finer by those able to experience them fully.

Thus Mill enlarged but retained Bentham's view that the happiness of all, considered impartially, is the standard of conduct. His account of how this standard relates to the fabric of everyday norms was charged with the nineteenth century's historical sense, but also maintained links with Bentham. Justice is a class of exceptionally stringent obligations on society - it is the 'claim we have on our fellow-creatures to join in making safe for us the

very groundwork of our existence' (1865b: 251). Because rights of justice protect this groundwork they take priority over the direct pursuit of general utility as well as over the private pursuit of personal ends.

Mill's doctrine of liberty dovetails with this account of justice. Here he appealed to rights founded on 'utility in the largest sense, grounded on the permanent interests of man as a progressive being' (1859: 224). The principle enunciated in his essay On Liberty (1859) safeguards people's freedom to pursue their own goals, so long as they do not infringe on the legitimate interests of others: power should not be exercised over people for their own good. Mill defended the principle on two grounds. It enables individuals to realize their potential in their own distinctive way, and, by liberating talents, creativity and energy, it institutes the social conditions for the moral development of culture and character.

1 Life

Mill was born in London on the 20 May 1806, the eldest son of a Scotsman, James Mill, and an English woman, Harriet Burrow. James educated his son himself - an education made famous by the account John Stuart gave of it in his *Autobiography* (1873). He taught John the classics, logic, political economy, jurisprudence and psychology - starting with Greek at the age of three. John was brought up in a circle of intellectual and political radicals, friends of his father, which included Jeremy Bentham and David Ricardo. In his twenties (not surprisingly, perhaps) he was afflicted by a deep depression from which he recovered partly through reading poetry. In those and subsequent years he also came to know some of the most interesting younger figures in English politics and culture. These included conservative critics of Benthamism, as well as radical adherents of it.

Mill followed his father into the East India Company, where he became an influential official, resigning only in 1858 when, following the Indian Mutiny, the Company was taken over by the Crown and the governance of India became the direct business of the British State. In 1851 he married Harriet Taylor, who in his own account greatly influenced his social philosophy. In the 1860s he was briefly a member of Parliament, and throughout his life was involved in many radical causes. Among them was his lifelong support for women's rights - see *The Subjection of Women* (1869).

Mill made his philosophical reputation with his *System of Logic*, published in 1843. The *Principles of Political Economy* (1848) was a synthesis of classical economics which defined liberal orthodoxy for at least a quarter of a century. His two best-known works of moral philosophy, *On Liberty* and *Utilitarianism*, appeared later - in 1859 and 1861. But he had been thinking about ethics and politics all his life, and it is his moral and political philosophy which is at present most widely read.

2 Language and logic

Nevertheless, Mill's epistemology and metaphysics remain as interesting and relevant as his better-known views in ethics and politics, and it is from these aspects of his philosophy that a general survey must start. In the *System of Logic* Mill distinguishes 'verbal' and 'real' propositions, and correspondingly, 'merely apparent' and 'real' inferences. An inference is merely apparent when no move to a new assertion has been made. For this to be so, the conclusion must literally have been asserted in the premises. In such a case, there can be no epistemological problem about justifying the apparent inference - there *is* nothing to justify. A verbal proposition can now be defined as a conditional proposition corresponding to a merely apparent inference. Propositions and inferences which are not verbal or merely apparent are real.

Mill argues that not only mathematics but logic itself contains real inferences. To demonstrate this he embarks on a semantic analysis of sentences and terms (he calls them 'propositions' and 'names'), of syllogistic logic and of the so-called 'Laws of Thought'. His analysis has imperfections and he does not unify it in a fully general account, but he supplies the foundations of such an account, and in doing so takes the empiricist epistemology of logic and mathematics to a new level.

The starting point is a distinction between the denotation and connotation of names. Names, which may be general or singular, denote things and connote attributes of things. A general name connotes attributes and denotes each object which has those attributes. Most singular names also connote attributes.

There is, however, an important class of singular names - proper names in the ordinary sense, such as

'Dartmouth' - which denote an object without connoting any property (see Proper names §§1, 6). Identity propositions which contain only non-connotative names, such as 'Tully is Cicero', are verbal, in Mill's view. They lack content in the sense that, according to Mill, the only information conveyed is about the names themselves: 'Tully' denotes the same object as 'Cicero' does. Mill's point is that there is no fact in the world to which 'Cicero is Tully' corresponds. But to class these propositions as verbal would require a change in the characterization of verbal propositions given above. Moreover, knowledge that Cicero is Tully is not a priori. We cannot know the proposition to be true just by reflecting on the meaning of the names - whereas Mill's overall intention is that the class of verbal propositions should be identical with the class of propositions which are innocuously a priori *because* they are empty of content. He does not comment on these difficulties.

The meaning of a declarative sentence - 'the import of a proposition' - is determined by the connotation, not the denotation, of its constituent names; the sole exception being connotationless proper names, where meaning is determined by denotation. (Again Mill does not explain how this thesis about the meaning of proper names is to be reconciled with the a posteriority of 'Cicero is Tully'.) Mill proceeds to show how the various syntactic forms identified by syllogistic theory yield conditions of truth for sentences of those forms, when the connotation of their constituent names is given.

Armed with this analysis he argues that logic contains real inferences and propositions. He assumes that to assert a conjunction, 'A and B', is simply to assert A and to assert B. He defines 'A or B' as 'If not A, then B, and if not B, then A'. 'If A then B' means, he thinks, 'The proposition B is a legitimate inference from the proposition A'. From these claims it follows that certain deductive inferences, for example, from a conjunction to one of its conjuncts, are merely apparent. But, Mill holds, the laws of contradiction and excluded middle are real - and therefore a posteriori - propositions. He takes it that 'not P' is equivalent in meaning to 'It is false that P'; if we further assume the equivalence in meaning of P and 'It is true that P', the principle of contradiction becomes, as he puts it, 'the same proposition cannot at the same time be false and true'. 'I cannot look upon this', he says, 'as a merely verbal proposition'. He makes analogous remarks about excluded middle, which turns - on these definitions - into the principle of bivalence: 'Either it is true that P or it is false that P'.

Mill adds an epistemological argument to this semantic analysis. If logic did not contain real inferences, all deductive reasoning would be a *petitio principii*, a begging of the question, and it could produce no new knowledge. Yet clearly it does produce new knowledge. So logic must contain real inferences.

Unfortunately, Mill mixes up this epistemological argument with an interesting but distinct objective. He wants to show that 'all inference is from particulars to particulars', in order to demystify the role that general propositions play in thought. He argues that in principle they add nothing to the force of an argument; particular conclusions could always be derived inductively direct from particular premises. Their value is psychological. They play the role of 'memoranda' or summary records of the inductive potential of all that we have observed, and they facilitate 'trains of reasoning' (for example, as in 'This is A; All As are Bs; No Bs are Cs; so this is not C'). Psychologically they greatly increase our memory and reasoning power, but epistemologically they are dispensable.

This thesis is connected to Mill's rejection of 'intuitive' knowledge of general truths and to his inductivism (see §5 below). But there is also a deeper way in which a radical empiricist must hold that all inference is from particulars to particulars. For consider the inference from 'Everything is F' to 'a is F'. Is it a real or merely apparent inference? It is impossible to hold it real if one also wishes to argue that real inferences are a posteriori. But the only way in which Mill can treat it as verbal is to treat the premise as a conjunction: 'a is F and b is F and…'. If that approach is precluded, then all that remains is to deny that 'Everything is F' is propositional - it must, rather, express an inferential commitment. Both approaches are very close to the surface in Mill's discussion of the syllogism, though neither emerges clearly.

3 Mathematics

The strategy which Mill applies to mathematics is broadly similar to his approach to logic. If it was merely verbal, mathematical reasoning would be a *petitio principii*, but semantic analysis shows that it contains real propositions.

Mill provides brief but insightful empiricist sketches of geometry and arithmetic. The theorems of geometry are deduced from premises which are real propositions inductively established. (Deduction is itself largely a process of real inference.) These premises, where they are not straightforwardly true of physical space, are true in the limit.

Geometrical objects - points, lines, planes - are ideal or ‘fictional’ limits of ideally constructible material entities. Thus the real empirical assertion underlying an axiom such as ‘Two straight lines cannot enclose a space’ is something like ‘The more closely two lines approach absolute breadthlessness and straightness, the smaller the space they enclose’.

Applying his distinction between denotation and connotation, Mill argues that arithmetical identities such as ‘Two plus one equals three’ are real propositions. Number terms denote ‘aggregates’ and connote certain attributes of aggregates. (He does not say that they denote those attributes of the aggregates, though perhaps he should have done.) ‘Aggregates’ are natural, not abstract, entities - ‘collections’ or ‘agglomerations’ individuated by a principle of aggregation. This theory escapes some of the influential criticisms Frege later made of it, but its viability none the less remains extremely doubtful. The respects in which aggregates have to differ from sets if they are to be credibly natural, and not abstract, entities are precisely those in which they seem to fail to produce a fully adequate ontology for arithmetic. (One can, for example, number numbers, but can there be aggregates of aggregates, or of attributes of aggregates, if aggregates are natural entities?)

However this may be, Mill’s philosophical programme is clear. Arithmetic, like logic and geometry, is a natural science, concerning a category of the laws of nature - those concerning aggregation. The fundamental principles of arithmetic and geometry, as well as of logic itself, are real. Mill provides the first thoroughly empiricist analysis of meaning and of deductive reasoning itself.

He distinguishes his view from three others - ‘Conceptualism’, ‘Nominalism’ and ‘Realism’. ‘Conceptualism’ is his name for the view which takes the objects studied by logic to be psychological states or acts. It holds that names stand for ‘ideas’ which make up judgments and that ‘a proposition is the expression of a relation between two ideas’. It confuses logic and psychology by assimilating propositions to judgments and attributes of objects to ideas. Against this doctrine Mill insists that:

> All language recognizes a difference between doctrine or opinion, and the fact of entertaining the opinion; between assent, and what is assented to…. Logic, according to the conception here formed of it, has no concern with the nature of the act of judging or believing; the consideration of that act, as a phenomenon of the mind, belongs to another science.
>
> (1843: 87)

The Nominalists - Mill cites Hobbes - hold that logic and mathematics are entirely verbal. Mill takes this position much more seriously than Conceptualism and seeks to refute it in detail. His main point is that Nominalists are only able to maintain their view because they fail to distinguish between the denotation and the connotation of names, ‘ seeking for their meaning exclusively in what they denote’ (1843: 91) (see Nominalism §3).

Nominalists and Conceptualists hold that logic and mathematics can be known non-empirically, while yet retaining the view that no real proposition about the world can be so known. Realists hold that logical and mathematical knowledge is knowledge of universals which exist in an abstract Platonic domain; the terms that make up sentences being signs that stand for such universals. Versions of this view were destined to stage a major revival in philosophy, and semantic analysis would be their main source, but it is the view Mill takes least seriously.

In the contemporary use of the term, Mill is himself a nominalist - he rejects abstract entities (see Abstract objects §4). However, just as severe difficulties lie in the way of treating the ontology of arithmetic in terms of aggregates rather than sets, so there are difficulties in treating the ontology of general semantics without appealing to universals and sets, as well as to natural properties and objects. We can have no clear view of how Mill would have responded to these difficulties had they been made evident to him. But we can be fairly sure that he would have sought to maintain his nominalism.

However, his main target is the doctrine that there are real a priori propositions (see A priori). What, he asks, goes on in practice when we hold a real proposition to be true a priori? We find its negation inconceivable, or that it is derived, by principles whose unsoundness we find inconceivable, from premises whose negation we find inconceivable. Mill is not offering a definition of what is meant by such terms as ‘a priori’, or ‘self-evident’; his point is that facts about what we find inconceivable are all that lends colour to the use of these terms.

They are facts about the limits, felt by us from the inside, on what we can imagine perceiving. Mill thought he

could explain these facts about unthinkability, or imaginative unrepresentability, in associationist terms, and much of his work claims to do so. This associationist psychology is unlikely nowadays to convince, but that does not affect his essential point: the step from our inability to represent to ourselves the negation of a proposition, to acceptance of its truth, calls for justification. Moreover, the justification itself must be a priori if it is to show that the proposition is known a priori.

4 'Psychologism' and naturalism

Mill is often mistakenly accused of 'psychologism' in his treatment of logic - an accusation which seems to go back to Husserl (and one which Frege does not make). 'Psychologism' is the view that laws of logic are psychological laws concerning our mental processes; or that 'meanings' are mental entities, and that 'judgments' assert relationships among these entities. But Mill's view, as we have seen, is that logic and mathematics are the most general empirical sciences, governing *all* phenomena. He explicitly holds that the distinction between necessary and contingent truths, understood 'metaphysically', is empty. And he dismisses the Conceptualist claim that names refer to ideas and propositions express or assert a psychological relation between them.

What explains, then, the attribution of 'psychologism' to Mill? Husserl quotes a passage from *An Examination of Sir William Hamilton's Philosophy* (1865a), which has been cited many times since:

> Logic is not the theory of Thought as Thought, but of valid Thought; not of thinking, but of correct thinking. *It is not a Science distinct from, and coordinate with Psychology. So far as it is a science at all, it is a part, or branch, of Psychology; differing from it, on the one hand as the part differs from the whole, and on the other, as an Art differs from a Science. Its theoretic grounds are wholly borrowed from Psychology, and include as much of that science as is required to justify the rules of the art.*
>
> (1865a: 359; italics show portion quoted by Husserl)

To give this a psychologistic reading is to take it out of context. Mill means that the logician must formulate rules of reasoning in a manner which will be as helpful as possible to inquirers, and must draw on the psychology of thought to do so. It is in that sense that the art of the logician borrows from the science of the psychologist. How best to promote the art of clear thinking is a psychological question. None the less,

> the laws, in the scientific sense of the term, of Thought as Thought - do not belong to Logic, but to Psychology: and it is only the *validity* of thought which Logic takes cognizance of.
>
> (1865a: 359)

So it is wrong to accuse Mill of psychologism about logic. But there is a sense in which his view of our most basic forms of inductive reasoning is psychologistic, or naturalistic. For how does he respond to the Kantian claim that the very possibility of knowledge requires that there be a priori elements in our knowledge? Even if we accept his inductive account of logic and mathematics, must we not accept the principle of induction itself as a priori?

For Mill, the primitive form of reasoning - in both the epistemological and the aetiological sense - is enumerative induction, the disposition to infer that all As are B from the observation of a number of As which are all B. (Or to the conclusion that a given percentage of all As are B from the observation of that percentage of Bs among a number of As.) We spontaneously agree in reasoning that way, and in holding that way of reasoning to be sound. This method of reasoning, enumerative induction, is not a merely verbal principle. So it cannot on Mill's own account be a priori. Mill says that we learn 'the laws of our rational faculty, like those of every other natural agency', by 'seeing the agent at work'. We bring our most basic reasoning dispositions to self-consciousness by critical reflection on our actual practice. He is right to say that this reflective scrutiny of practice is, in a *certain* sense, an a posteriori process. It examines dispositions which we have before we examine them. Having examined our dispositions, we reach a reflective equilibrium in which we endorse some - and perhaps reject others. We endorse them as sound norms of reasoning. There is nothing more to be said: no further story, platonic or transcendental, to be told.

Unlike Hume, or even Reid, Mill shows no interest at all in scepticism. If one thinks that scepticism is both unanswerable and unserious this may be true philosophic wisdom. But to Mill's epistemological critics, whether they were realists or post-Kantian idealists, it seemed obvious that it was evasion, not wisdom. Naturalism could only seem to differ from scepticism by being uncritical, and in this we find the truth in the allegation that Mill's

system of logic is 'psychologistic'; if it is sound criticism, it is sound criticism of all naturalistic epistemology.

5 Inductive science

Mill does not raise purely sceptical questions about simple generalization from experience; he none the less thinks it a highly fallible method. His aim is to show how reasoning methods can evolve from it which greatly reduce the fallibility of induction, even though they can never wholly eliminate it.

Humankind begins with 'spontaneous' and 'unscientific' inductions about particular unconnected natural phenomena or aspects of experience. As these generalizations accumulate and interweave, they justify the second-order inductive conclusion that *all* phenomena are subject to uniformity, and more specifically, that all have discoverable sufficient conditions. In this less vague form, the principle of general uniformity becomes, given Mill's analysis of causation, the Law of Universal Causation. It in turn provides (Mill believes) the grounding assumption for a new style of reasoning about nature - eliminative induction.

In this type of reasoning, the assumption that a type of phenomenon has uniform causes, together with a (revisable) assumption about what its possible causes are, initiates a comparative inquiry in which the actual cause is identified by elimination. Mill formulates the logic of this eliminative reasoning in his well-known 'Methods of Experimental Inquiry' (Chapter 7, Book 2 of *System of Logic*). (A full account is given in Mackie (1974).) His picture of the interplay between enumerative and eliminative reasoning, and of the way it entrenches, from within, our rational confidence in the inductive process, is elegant and penetrating.

The improved scientific induction which results from this new style of reasoning spills back onto the principle of Universal Causation on which it rests, and raises its certainty to a new level. That in turn raises our confidence in the totality of particular enumerative inductions from which the principle is derived. So the amount of confidence with which one can rely on the 'inductive process' as a whole depends on the point which has been reached in its history - though the confidence to be attached to particular inductions always remains variable.

Mill's inductivism - his view that enumerative induction is the only ultimately authoritative method of inference to new truths - was rejected by William Whewell (see Whewell, W. §2), who argued that the really fundamental method in scientific inquiry was the Hypothetical Method, in which one argues to the truth of a hypothesis from the fact that it would explain observed phenomena (see Inference to the best explanation). Mill had read Whewell's *History of the Inductive Sciences* (1837), and could hardly fail to be aware of the pervasiveness of hypotheses in the actual process of inquiry, or of their indispensability in supplying working assumptions - their 'heuristic' value, as Whewell called it. But what Mill could not accept was that the mere fact that a hypothesis accounted for the data in itself provided a reason for thinking it true.

Yet Whewell's appeal was to the actual practice of scientific reasoning, as observed in the history of science. An appeal of that kind was precisely what Mill, on his own principles, could not ignore. If the disposition to hypothesize is spontaneous, why should it not be recognized as a fundamental method of reasoning to truth, as enumerative induction is?

Mill's refusal to recognize it is not arbitrary. The essential point underlying it is a powerful one: it is the possibility that a body of data may be explained equally well by more than one hypothesis. Mill does not deny the increasingly deductive and mathematical organization of science - he emphasizes it. That is quite compatible with his inductivism, and indeed central to his account of the increasing reliability of the inductive process. He further agrees that a hypothesis can sometimes be shown, by eliminative methods of inductive reasoning which he accepts, to be the only one consistent with the facts. And he allows various other cases of apparently purely hypothetical reasoning which are, in his view, genuinely inductive.

When all such cases have been taken into account, we are left with pure cases of the Hypothetical Method, in which the causes postulated are not directly observable, and not simply because they are assumed to operate - in accordance with known laws, inductively established - in regions of time or space too distant to observe. What are we to say of such hypotheses? For example of the 'undulatory' theory of light? They cannot, Mill says, be accepted as inductively established truths, not even as probable ones.

> An hypothesis of this kind is not to be received as probably true because it accounts for all the known phenomena; since this is a condition sometimes fulfilled tolerably well by two conflicting hypotheses; while

> there are probably many others which are equally possible, but which from want of anything analogous in our experience, our minds are unfitted to conceive.
>
> (1843: 500)

Such a hypothesis can suggest fruitful analogies, Mill thinks, but cannot be regarded as yielding a new truth itself. The data do not determine a unique hypothesis: it is this possibility of underdetermination which stops him from accepting hypothetical reasoning as an independent method of achieving truth.

In seeing the difficulty Mill is certainly on solid ground. What he does not see, however, is how much must be torn from the fabric of our belief if inductivism is applied strictly. So it is an important question whether the difficulty can be resolved - and whether it can be resolved within a naturalistic framework which does not appeal to an underlying idealism, as Whewell did. If naturalism can endorse the hypothetical method, then among other things it can develop a more plausible empiricism about logic and mathematics than Mill's. But the ramifications of his inductivism are even wider, as becomes apparent from an examination of his general metaphysics.

6 Mind and matter

Mill sets out his metaphysical views in *An Examination of Sir William Hamilton's Philosophy*. Hamilton was the last eminent representative of the Scottish Common Sense School, and a ferocious controversialist - in Mill's eyes a pillar of the right-thinking establishment, ripe for demolition. The result is that Mill's discussion of general metaphysical issues is cast in a highly polemical form which leaves important issues shrouded in obscurity. He does however give himself space to develop his view of our knowledge of the external world.

He begins with a doctrine which he rightly takes to be generally accepted (in his time) on all sides: 'that all the attributes which we ascribe to objects, consist in their having the power of exciting one or another variety of sensation in our minds; that an object is to us nothing else than that which affects our senses in a certain manner' (1865a: 6). This is 'the doctrine of the Relativity of Knowledge to the knowing mind'. It makes epistemology, in Mill's words, the 'Interpretation of Consciousness'. He proceeds to analyse what we mean when we say that objects are external to us:

> We mean, that there is concerned in our perceptions something which exists when we are not thinking of it; which existed before we had ever thought of it, and would exist if we were annihilated; and further, that there exist things which we never saw, touched or otherwise perceived, and things which have never been perceived by man. This idea of something which is distinguished from our fleeting impressions by what, in Kantian language, is called Perdurability; something which is fixed and the same, while our impressions vary; something which exists whether we are aware of it or not, constitutes altogether our idea of external substance. Whoever can assign an origin to this complex conception, has accounted for what we mean by the belief in matter.
>
> (1865a: 178-9)

To assign this origin Mill postulates that

> we are capable of forming the conception of Possible sensations; sensations which we are not feeling at the present moment, but which we might feel, and should feel if certain conditions were present.
>
> (1865a: 177)

> These possibilities, which are conditional certainties, need a special name to distinguish them from mere vague possibilities, which experience gives no warrant for reckoning upon. Now, as soon as a distinguishing name is given, though it be only to the same thing regarded in a different aspect, one of the most familiar experiences of our mental nature teaches us, that the different name comes to be considered as the name of a different thing.
>
> (1865a: 179-80)

Physical objects are 'Permanent Possibilities of Sensation' (There is a change in the 'permanent' possibilities of sensation whenever there is change in the world. Mill also uses other terms, such as 'certified' or 'guaranteed'.) We often find that whenever a given cluster of certified possibilities of sensation obtains, then a certain other cluster follows. 'Hence our ideas of causation, power, activity…become connected, not with sensations, but with

groups of possibilities of sensation' (1865a: 181) (see Phenomenalism §1).

However, even if our notion of matter as the external cause of sensations can be explained on psychological principles, it is still possible to hold that good grounds can be given for thinking the notion to have instances. There might be a legitimate inference from the existence of the permanent possibilities and their correlations to the existence of an external cause of our sensations. It is at just this point that Mill's inductivism plays a part. The inference would be a case of hypothetical reasoning, to an explanation of experience which transcended all possible data of experience; and that is precisely what Mill rejects: 'I assume only the tendency, but not the legitimacy of the tendency, to extend all the laws of our own experience to a sphere beyond our experience' (1865a: 187).

If matter is the permanent possibility of sensation what is mind? Can it also be resolved into 'a series of feelings, with a background of possibilities of feeling'? Mill finds in this view a serious difficulty: to remember or expect a state of consciousness is not simply to believe that it has existed or will exist; it is to believe that *I myself* have experienced or will experience that state of consciousness.

> If, therefore, we speak of the Mind as a series of feelings, we are obliged to complete the statement by calling it a series of feelings which is aware of itself as past and future; and we are reduced to the alternative of believing that the Mind, or Ego, is something different from any series of feelings, or possibilities of them, or of accepting the paradox, that something which *ex hypothesi* is but a series of feelings, can be aware of itself as a series.
>
> (1865a: 194)

Thus although Mill is unwilling to accept 'the common theory of Mind, as a so-called substance', the self-consciousness involved in memory and expectation drives him to 'ascribe a reality to the Ego - to my own Mind - different from that real existence as a Permanent Possibility, which is the only reality I acknowledge in Matter' (1865a: 208).

This ontology, Mill thinks, is consistent with common sense realism about the world. Phenomenalism - the conception of matter as possibility of experience - allegedly leaves common sense and science untouched. In particular, mind and experience is still properly seen as a part of the natural order.

Yet if phenomenalism is right, only the experiences are real. Mill thinks we are led to that conclusion by the very standards of reasoning recognized in a naturalistic 'science of science', or 'system of logic'. If he is right, then the naturalistic vision of the world which sees minds as part of a larger causal order is self-undermining. For if we are led to the conclusion that only states of consciousness are real by *an application of naturalism's own standards*, then that conclusion has to be understood on the same level as the naturalistic affirmation that states of consciousness are themselves part of a larger causal order external to them - and therefore as inconsistent with it. Causal relations cannot exist between fictional entities which are mere markers for possibilities of sensation.

This is the fault-line in Mill's epistemology and metaphysics. Either naturalism undermines itself, or there is something wrong with Mill's inductivist analysis of our natural norms of reasoning, or with his endorsement of the doctrine of the Relativity of Knowledge, or with both. It is not obvious that Mill's most fundamental tenet - his naturalistic view of the mind - can be safeguarded by rejecting inductivism and endorsing the hypothetical method. There is still something implausible about hypothesizing the world as an explanation of pure experience. Mill himself explicitly acknowledged that memory, as well as induction, has epistemic authority. Had he analysed the significance of such an acknowledgment more thoroughly, he might have noted a parallel: on the one hand a primitive epistemic norm which warrants assertions about the past based on present memory-experiences; on the other, primitive epistemic norms which warrant assertions about the physical world based on perceptual experience. But perhaps that would have taken him too far in the direction of Reid's principles of common sense.

7 Freedom and the moral sciences

The sixth and last book of the *System of Logic* is a classical statement of methodology in the 'moral' sciences (that is, the human sciences). Its strength derives partly from the fact that Mill was a philosopher who also practised the whole range of these sciences as they then stood. He was mainly known as a political economist, but had strong interests in psychology and in the nascent science of sociology. He thought as an economist as well as a

philosopher about socialism, taxation and systems of property, and he thought in sociological terms about such topics as democracy and the role of moral and intellectual elites. He also took an interest in a variety of psychological topics, including desire, pleasure and will, and the origins of conscience and justice.

The phenomena of mind and society are, in Mill's view, causal processes. If mind and society are part of the causal order, and causation is regular succession, then the general model of explanation he has proposed, according to which explanation subsumes facts under laws linking them to their causal antecedents, will apply, he thinks, to the moral sciences. It may be hard for moral science to live up to it, in view of the complexity of its data, but the model stands as an ideal. Important issues remain about the character of and relationships between the various moral sciences, and Mill treats these issues in detail. But he does not think that the very idea of a moral science raises new metaphysical or epistemological problems (see Explanation in history and social science §3).

Psychological concepts are intentional and, correspondingly, the moral sciences are interpretative. Can laws of individual behaviour be formulated, as Mill assumed, in this interpretative vocabulary? His analysis of the moral sciences takes their fundamental laws to lie in the domain of psychology. He was familiar with a different view, that of Auguste Comte, who held that the fundamental and irreducible moral science was sociology (a term coined by Comte). There was no deeper moral science, no science of psychology; the next level below sociology was the physical science of biology. Mill rejected that view, but enthusiastically shared Comte's vision of a historical sociology. Psychology may be the irreducible theoretical basis of the moral sciences; historical sociology is to be, as far as Mill was concerned, their prime exhibit.

Associationism and a Comtean historical sociology are thus the driving ideas in Mill's logic of the moral sciences. They interlock. Associationism fortifies his belief in the mutability of human nature: different social and historical formations can build radically different patterns of association. The bridge between historical sociology and the invariant laws of associationist psychology can be provided, Mill thinks, by an innovation of his own: a science he calls 'Ethology', which will study the different forms of human character in different social formations. He intended to write a treatise on the subject; significantly, he failed.

How, on this naturalistic view of mind and society, can human beings be free? The question mattered deeply to Mill. The conclusion others drew from the doctrine of determinism, namely, that we have (in Mill's phrase) no 'power of *self*-formation', and hence are not really responsible for our character or our actions, would have destroyed his moral vision. Self-formation is the fulcrum of his ideal of life, and 'moral freedom', the ability to bring one's desires under the control of a steady rational purpose, is a condition of self-formation, of having a character in the full sense (see Free will §§3-4).

Thus Mill had to show how causally conditioned natural objects can also be morally free agents. The sketch of a solution in the *System of Logic* (Book 6, chapter 2), which Mill thought the best chapter in the book, is brief but penetrating. (There is a longer discussion in *An Examination of Sir William Hamilton's Philosophy*, chapter 26.) One of its leading features is a distinction between resistible and irresistible causes; 'in common use', only causes which are 'irresistible', whose operation is 'supposed too powerful to be counteracted at all', are called necessary:

> There are physical sequences which we call necessary, as death for want of food or air; there are others which, though as much cases of causation as the former, are not said to be necessary, as death from poison, which an antidote, or the use of the stomach-pump, will sometimes avert…human actions are in this last predicament: they are never (except in some cases of mania) ruled by any one motive with such absolute sway, that there is no room for the influence of another.

(1843: 839)

An action caused by an irresistible motive (a 'mania') is plainly not free. This is certainly very pertinent. Yet something is added when we move from the idea of motives being resistible by other motives to the idea of moral freedom, the idea that *I* have the power to resist motives. It is the ability to recognize and respond to reasons. I act freely if I could have resisted the motive on which I in fact acted, had there been good reason to do so. A motive impairs my moral freedom if it cannot be defeated by a cogent reason for not acting on it. Mill fails to bring this connection between freedom and reason into clear view, but he relies on it in his ethical writings. He takes it that I am more or less free overall, according to the degree to which I can bring my motives under scrutiny and act on the result of that scrutiny. So I can *make* myself more free, by shaping desires or at least cultivating the strength of

will to overcome them.

> A person feels morally free who feels that his habits or his temptations are not his masters, but he theirs: who even in yielding to them knows that he could resist…we must feel that our wish, if not strong enough to alter our character, is strong enough to conquer our character when the two are brought into conflict in any particular case of conduct. And hence it is said with truth, that none but a person of confirmed virtue is completely free.
>
> (1843: 841)

The identification of moral freedom with confirmed virtue, and (less explicitly) of confirmed virtue with steady responsiveness to reasons, is present in Mill as in Kant (see Kant, I. §11). But Mill does not address crucial questions such as what is it to grasp a reason, or how reason can be efficacious. To vindicate the coherence of his view one would have to show how to answer such questions in a way which is compatible with naturalism. The problem remains central in contemporary philosophy - certainly Mill himself never took full stock of it.

8 Happiness, desire and will

Mill's single ultimate standard of theoretical reason is enumerative induction. His single ultimate standard of practical reason is the principle of utility; its standard is the good of all. But what is the good? According to Mill, it is happiness, understood as 'pleasure, and freedom from pain' (1861a: 210) (see Happiness). His case rests on the following principle of method:

> The sole evidence it is possible to produce that anything is desirable, is that people do actually desire it. If the end which the utilitarian doctrine proposes to itself were not, in theory and in practice, acknowledged to be an end, nothing could ever convince any person that it was so.
>
> (1861a: 234)

Mill is not claiming that the conclusion that happiness is desirable follows deductively from the premise that people in general desire it. He gives some ground for that misinterpretation when he compares the move from 'desired' to 'desirable' to those from 'seen' and 'heard' to 'visible' and 'audible'. Nevertheless, his procedure is simply an appeal to reflective practice, just as in the case of enumerative induction - where again the 'sole evidence' that enumerative induction is an ultimate norm of reasoning is that we acknowledge it as such 'in theory and in practice'.

However, a question which is appropriate by Mill's own principle of method is whether reflective practice shows that happiness is the *only* thing we desire. Do not human beings, in theory and in practice, desire things other than happiness? Mill anticipates this question and responds to it at length. He claims that when we want a particular object for its own sake and with no further end in view (let us say, when we have an underive*d* desire for it), then we desire it because we think of it as enjoyable: 'to desire anything, except in proportion as the idea of it is pleasant, is a physical and metaphysical impossibility' (1861a: 238). But this does not mean that we desire all objects as *means* to our pleasure. The desire for an object is genuinely a desire for that *object*; it is not the desire for pleasure as such. Mill's way of marking this is to say that the object is desired as a 'part' or an 'ingredient' of happiness, not as a means to it. His rejection of psychological egoism was one of the points on which he took himself to be at odds with Bentham (see Bentham, J. §3). When a person does something because they think it will be pleasant - for example a generous person who gives a present - it does not follow that they are acting selfishly (see Egoism and altruism). Generous people take pleasure in the prospect of giving, not in the prospect of getting pleasure; their desire to give is not derived from the desire to get pleasure. Giving is a part of their happiness, not a means to it.

Thus Mill's case for the claim that happiness is the sole human end, put more carefully, is this: 'Whatever is desired otherwise than as a means to some end beyond itself, and ultimately to happiness, is desired as itself a part of happiness, and is not desired for itself until has become so' (1861a: 237). Nothing here assumed Hume's view that every action must ultimately flow from an underived desire. That is a quite separate issue, and Mill's view of it is closer to that of Kant or Reid than to that of Hume. He insists 'positively and emphatically'

> that the will is a different thing from desire; that a person of confirmed virtue, or any other person whose purposes are fixed, carries out his purposes without any thought of the pleasure he has in contemplating them,

> or expects to derive from their fulfilment.
>
> (1861a: 238)

This distinction between purpose and desire is central to Mill's conception of the will. When we develop purposes we can will against mere likings or aversions: 'In the case of an habitual purpose, instead of willing the thing because we desire it, we often desire it only because we will it' (1861a: 238). Every action is caused by a motive, but not every motive is a liking or aversion:

> When the will is said to be determined by motives, a motive does not mean always, or solely, the anticipation of a pleasure or of a pain…. A habit of willing is commonly called a purpose; and among the causes of our volitions, and of the actions which flow from them, must be reckoned not only likings and aversions, but also purposes.
>
> (1843: 842)

The formation of purposes from desires is the evolution of will; it is also the development of character. Mill quotes Novalis: 'a character is a completely fashioned will' (1843: 843). Not that this reflects the whole of his view of character; character for him requires the cultivation of feeling as well as the cultivation of will: 'A person whose desires and impulses are his own - are the expression of his own nature, as it has been developed and modified by his own culture - is said to have a character' (1859: 264). Developed spontaneity of feeling is part of fully-perfected character, but certainly moral freedom is too - 'none but a person of confirmed virtue is completely free'. As noted in §7 above, Mill does not address the crucial question of what it is for a purpose to be informed by reason. Still, the distinction between purpose and desire does allow him to recognize conscientious action, action which flows not from any inclination but solely from a habit of willing; he asserts the possibility and value of a 'confirmed will to do right' (1861a: 238), distinct from motives of anticipated pleasure and pain. That 'virtuous will', however, is not for him an intrinsic good, as it is for Kant. It is

> a means to good, not intrinsically a good; and does not contradict the doctrine that nothing is good to human beings but in so far as it is either itself pleasurable, or a means of attaining pleasure or averting pain.
>
> (1861a: 239)

9 Qualities of pleasure

Happiness - pleasure and the absence of pain - is the sole final end of life. But Mill's idea of it is altogether more romantic and liberal than that of earlier utilitarians. He takes into account the fact that a variety of notions - for example, purity, elevation, depth, refinement and sublimity, and their opposites - enter into our assessments of pleasure. We do not assess pleasures along a single dimension. In his general ethical and political writing, Mill freely draws on that extensive and flexible language. He sees the need to recognize it also in utilitarian theory, but here he does so rather more mechanically by distinguishing 'quality' and 'quantity' of pleasure. From the first publication of *Utilitarianism*, at least three sorts of question have been asked about this famous distinction. The first is whether it is reconcilable with hedonism. The second is epistemological: is there a cogent way of establishing that some pleasures are superior in 'quality'? The third question, perhaps the most challenging, though less often discussed, is how the distinction fits into the framework of utilitarianism.

As to the first question: there is indeed, as Mill says, no reason in logic why more than one characteristic of pleasures should not be relevant to estimating their value - though if we call those characteristics 'quantity' and 'quality', we need to maintain a careful distinction between the quantity and quality of a pleasure on the one hand and its degree of value on the other. All that hedonism requires is that the only things that make a pleasure valuable are its characteristics as a *pleasure* (see Hedonism).

Nevertheless, an impression lingers that Mill's discussion appeals to intuitions which are not hedonistic. For example:

> Few human creatures would consent to be changed into any of the lower animals, for a promise of the fullest allowance of a beast's pleasures; no intelligent human being would consent to be a fool, no instructed person would be an ignoramus, no person of feeling and conscience would be selfish and base, even though they should be persuaded that the fool, the dunce, or the rascal is better satisfied with his lot than they are with

theirs.

(1861a: 211)

He also notes that a 'being of higher faculties requires more to make him happy, is capable probably of more acute suffering, and is certainly accessible to it at more points, than one of an inferior type' (1861a: 212). So a being of higher faculties may be faced with a choice: on the one hand a life of acute suffering, with no access to any of the higher pleasures which its faculties make it capable of appreciating, on the other, a cure (for example, an operation) which relieves its suffering but leaves it only with the pleasures available to a fool or a dunce. Is Mill saying that in *all* such cases the life of suffering should be preferred? He does not say so explicitly and if he does adhere to hedonism he should not. For cases are surely possible in which life after the cure offers a stream of pleasures more valuable overall, taking quality as well as quantity into account, than the life of suffering in which one retains one's higher faculties but is bereft of higher pleasures.

What of the epistemological question? Mill compares assessments of the comparative quality of pleasures to assessments of their comparative quantity: both are determined by 'the feelings and judgments of the experienced' (1861a: 213). But a judgment that the pleasure derived from film A is of a higher kind than that derived from watching film B is clearly, as Mill conceives it, an evaluative judgment. The proper comparison would have been with the evaluative judgment that pleasure as such is desirable. And Mill could have said that with this judgment, as with basic evaluative judgments in general, the only criterion is reflective practice - self-examination and discussion. In such discussion, some people emerge as better judges than others - this is not a circularity but an inherent feature of normative judgment.

Yet now the third question becomes pressing: how are such judgments of the quality of pleasures to be registered in the utilitarian calculus? In requiring utilitarianism to take them into account Mill makes a move of political as well as ethical significance. For what rank do we give to these pleasures in our social ordering - the rank which highly developed human natures attach to them or that which lower human natures attach to them? Mill's answer is unambiguous: it is the verdict of 'competent judges' which stands.

Suppose that beings of highly developed faculties place the pleasures of scientific discovery or artistic creation so much higher than those of material well-being that (above a certain modicum of physical comfort and security) any amount of the former, however small, is ranked by them above any amount of the latter, however large. Suppose, however, that beings of considerably less developed faculties would not share this assessment. And now suppose that the question is put to Mill, how much of the lower pleasure of the less developed being may be sacrificed to maintain the more highly developed being's higher pleasure? Mill's view is that the more highly developed being delivers the correct assessment of the relative value of the higher and lower pleasures. But, by hypothesis, it would be prepared to sacrifice any amount of the lower pleasure, down to a modicum of physical comfort and security, for the smallest amount of the higher. Must the same hold for the interpersonal case? Must it be correct for the utilitarian to sacrifice any amount of the lower pleasures of lower beings, down to a level at which they are provided with the modicum of comfort and security, in order to secure some higher pleasure for a higher being? Mill provides no answer.

10 The utility principle

Though Mill deepened the utilitarian understanding of pleasure, desire, character and will, he never adequately re-examined the principle of utility itself. When he states the utilitarian doctrine before considering what kind of proof can be given of it, he states it thus: 'Happiness is desirable, and the only thing desirable, as an end, all other things being only desirable as means to that end' (1861a: 210). In effect, he takes his task to be that of demonstrating the truth of hedonism. All he has to say about the move from hedonism to the utility principle is that if 'each person's happiness is a good to that person' then 'the general happiness' must be 'a good to the aggregate of all persons'. In a letter in which he explains this unclear remark, he says: 'I merely meant in this particular sentence to argue that since A's happiness is a good, B's a good, C's a good, etc, the sum of all these goods must be a good' (1972: 1414). This contains two inexplicit assumptions. The more obvious point is that an egoist may accept that Mill has shown that 'each person's happiness is a good to that person', but deny that he has shown that happiness is a good tout *court*. The egoist denies that Mill has shown that *everyone* has reason to promote the happiness of anyone. That requires a separate postulate, as Henry Sidgwick pointed out.

The second inexplicit assumption is more subtle. At the end of the last chapter of *Utilitarianism*, 'On the Connexion between Justice and Utility', Mill does explain that he takes 'perfect impartiality between persons' to be part of the very meaning of the Greatest Happiness Principle:

> That principle is a mere form of words without rational signification, unless one person's happiness, supposed equal in degree (with the proper allowance made for kind), is counted for exactly as much as another's. Those conditions being supplied, Bentham's dictum, 'everybody to count for one, nobody for more than one', might be written under the principle of utility as an explanatory commentary.
>
> (1861a: 257)

So here Mill supplies the required postulate of impartiality. However, the concept of impartiality does not, on its own, yield utilitarianism's aggregative principle of distribution. Maximizing the *sum* of individuals' happiness, if it makes sense to talk in this way at all, is one way of being impartial: no individual's happiness is given greater weight than any other's in the procedure which determines the value of a state of affairs as a function of the happiness of individuals in that state of affairs. In this sense the procedure implements the principle, 'Everybody to count for one, nobody for more than one'; but so does maximizing the average of all individuals' unweighted happiness. Here too all individuals count for one and no more than one. In fact a wide variety of non-equivalent distributive principles is impartial in this way. The most one could get from combining a postulate of impartiality with hedonism is that ethical value is a positive impartial function of individual happiness and of nothing else. In a footnote to the paragraph Mill glosses the requirement of perfect impartiality as follows: 'equal amounts of happiness are equally desirable, whether felt by the same or by different persons'. That does yield aggregative or average utilitarianism, but it follows neither from the thesis that happiness is the only thing desirable to human beings, nor from the formal notion of impartiality (see Impartiality §2).

11 Morality and justice

When we turn to Mill's conception of the relationship between the utility principle and the fabric of principles which regulate everyday social life, we find him again at his most impressive. He stresses that a utilitarian standard of value cannot itself tell what practical rules, aims or ideals we should live by. In his autobiography he dates this conviction to the period of his mental crisis. He now 'gave its proper place, among the prime necessities of human well-being, to the internal culture of the individual' (1873: 145-7). The prime task for human beings was to attend to that internal culture - to develop whatever was best in themselves. The indirect role in which he now cast the utility principle became a fundamental structural feature of his moral and political philosophy. For example, he accuses Auguste Comte of committing:

> the error which is often, but falsely, charged against the whole class of utilitarian moralists; he required that the test of conduct should also be the exclusive motive of it…. M. Comte is a morality-intoxicated man. Every question with him is one of morality, and no motive but that of morality is permitted.
>
> (1865b: 335-6)

Mill gives a succinct statement of his own doctrine at the end of the *System of Logic*. As always, he affirms 'that the promotion of happiness is the ultimate principle of Teleology'. But, he continues,

> I do not mean to suggest that the promotion of happiness should be itself the end of all actions, or even of all rules of action. It is the justification, and ought to be the controller, of all ends, but is not itself the sole end…. I fully admit that…the cultivation of an ideal nobleness of will and conduct, should be to individual human beings an end, for which the specific pursuit either of their own happiness or of that of others (except so far as included in that idea) should, in any case of conflict, give way. But I hold that the very question, what constitutes this elevation of character, is itself to be decided by a reference to happiness as the standard.
>
> (1843: 952)

The happiness of all is 'the test of all rules of conduct' - and not only rules of conduct but also of cultivation of feelings. How is the test applied? Here Mill learned more from Coleridge (§2) than from Bentham; that is, from historical criticism directed at the abstract social visionaries of the enlightenment. They did not see that moral sentiments can only grow in a stable tradition and social setting. They did not grasp the conditions necessary for such a tradition and setting - education of personal impulses to a restraining discipline, shared allegiance to some

enduring and unquestioned values, 'a strong and active principle of cohesion' among 'members of the same community or state'. Hence

> They threw away the shell without preserving the kernel; and attempting to new-model society without the binding forces which hold society together, met with such success as might have been anticipated.
>
> (1840: 138)

This feeling for the historicity of social formations and genealogies of morals gives Mill's ethical vision a penetration which is absent from Bentham (and also from the excessively abstract discussions of utilitarianism in twentieth-century philosophy). On the other hand the analysis of morality, rights and justice which Mill fits into this ethical vision owes much to Bentham.
